#### **INF-GEO 4310 Imaging**

Lecture 28.10.2013

Fritz Albregtsen

- Themes today:
- Introduction to imaging
- Geometrical optics Reflection
- Geometrical optics Refraction
- Literature:
- F. Albregtsen: "1. Imaging an introduction" (8 pages)
- F. Albregtsen: "2. Reflection, refraction, diffraction, and scattering" (the first 36 of 82 pages)

28.10.2013	INF-GEO 4310	1	28.10.2013	INF-GEO 4310

## Image not created by imaging

#### Image dimensions

Imaging

Imaging is a process that produces an image

Rendering a mathemathical function is not

considered to be imaging, but visualization.

• The image that is produced may be projected

onto a screen for viewing, or it may be

matrix for storage and processing.

captured on film or some digital detector

of some part of our surroundings.

- Image may be a 2-D matrix of intensity values.
- 2-D images at several wavelengths => 3-D image.
- Time-instances of 3-D image => 4-D image.
- 3-D medical image (US, CT, MR, PET) or seismic
  - 3-D image at several frequencies => 4-D image
  - 4-D image at several instances in time => 5-D image.

INF-GEO 4310

3

# Passive imaging

- Utilizes energy sources external to imaging system

   usually naturally available sources.
- Either using image sources present in the scene, or letting source light up objects within the scene.
- Examples:

28.10.2013

- infrared (IR) imaging of
  - heat sources
  - leaks in a construction.
- Astronomical images of
  - Visual, gamma, X-ray, UV, IR, MW and radio sources.

INF-GEO 4310

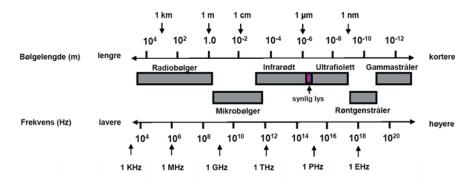

- We image radiation reflected at a given wavelength, or absorbed and reemitted at a different wavelength.
- Different objects or different parts of the same object may have different absorption / reflection properties.
  - Highly absorbing objects look dark
  - Spectral absorption determine color of object.
- Reflection properties determine whether objects are
  - Mirror-like (specular reflection)
  - Matte surfaces (diffuse reflection).
- Orientation, shape and fine structure of surface, influence how the object is imaged.

28.10.2013	28.	10	.201	3

INF-GEO 4310

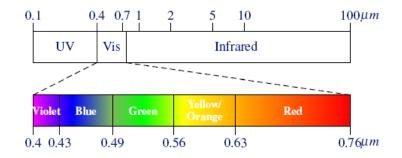

Wavelength and frequency

#### The electromagnetic spectrum:

#### The visual part of the spectrum

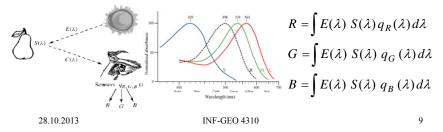

# Human eye responds to radiation in $0.4 - 0.7 \ \mu m$ range

5

## Color of images

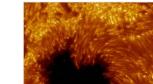

- Light from the Sun, having a spectral distribution  $\mathsf{E}(\lambda)$  falls on object.
- Surface of object has a spectral reflection function  $\mathsf{S}(\lambda).$
- Light entering the eye is detected by the three cone types,
   each having a spectral sensitivity function, g(λ).
- CIE-defined RGB primaries:
  - Blue=436 nm, Green=546 nm, Red=700.0 nm,
  - $\ -$  and standard light sensitivity curves for the three color components.
- Three analog signals expressing a three-channel image by integrals:

# Pseudo-color images

- Are single-channel (graylevel) images where a color has been assigned to each graylevel.
- Example: Sunspot image.
  - Monochromatic filter gives graylevel image.
  - Lookup-table maps each graylevel to an RGB-value.
- Used extensively in many imaging modalities!

28.10.2013

INF-GEO 4310

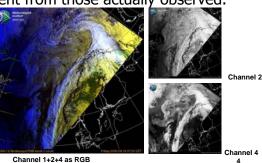

10

# False-color images

- We have graylevel images from three wavelengths.
- Assign each of them to the primary colors in (RGB), even though wavelengths do not correspond to (RGB).
- The result is an image of the observed scene using colors that are different from those actually observed.

INF-GEO 4310

- Ex.: NOAA AVHRR
- Three images:
  - 580-680 nm
  - 725 1 000 nm
  - 1 030 1 130 nm
- displayed as RGB (435, 546, 700 nm)

11

## Geometrical optics: Reflection

- Reflectance
- Diffuse and specular reflection
- Imaging by planar mirrors and retro-reflectors
- Sign rules for image formation
- Imaging by curved mirrors
   Spherical mirrors
  - Optical aberrations
- Optical and
   non-optical telescopes

#### Reflection

- Reflection occurs when a wave hits the interface between two dissimilar media,
  - $\ensuremath{\,-\,}$  at least part of the wave returns into the medium of origin.
- Common examples:
  - reflection of rays of light
  - reflection of surface waves
    - Surface waves in a pool of water
    - Sound waves reflected as echo from a wall
- Reflection may be
  - Specular: occurs on a blank mirroring surface that retains the geometry of the beams of light.
  - Diffuse: occurs on a rougher surface, not retaining the imaging geometry, only the energy.

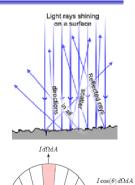

Reflectance
-------------

- The ratio of reflected power to incident power, generally expressed in dB or %.
- Reflectance varies with the angle of incidence.
- Reflectance varies with wavelength.
- Surface reflectance is often divided into
  - diffuse reflectance
  - specular reflectance
- In climatology, reflectance is called albedo.
- Also important in computer graphics.

28.10.2013	INF-GEO 4310	13	28.10.2013	INF-GEO 4310	14

# Diffuse reflection

- A rough surface does not form an image.
- Lambert's cosine law of diffuse reflection:
  - The total radiant power observed from a "Lambertian" surface is directly proportional to the cosine of the angle  $\theta$  between the observer's line of sight and the surface normal.
- When an area element is viewed from any angle, it has the same radiance.
- Although the emitted power from an area element is reduced by the cosine of the emission angle, the observed size of the area element is also reduced by that same amount.

#### Specular reflection

 In specular reflection, the angle of incidence θ<sub>i</sub> equals the angle of reflection θ<sub>r</sub>.

.....

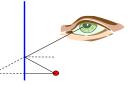

- Reflection occurs when light travels from a medium of a given refractive index into a medium with a different refractive index.
  - A fraction is reflected from the interface
  - The remainder is refracted into the transparent medium.
- Common examples of specular light reflection:
  - Mirror (a glass sheet in front of a metallic coating)
  - Surface of transparent media, such as water or glass.

#### "Perfect" mirrors

- A **perfect mirror** reflects light (and electromagnetic radiation in general) perfectly, and doesn't transmit it.
- Domestic mirrors are not perfect mirrors.
- Dielectric mirrors are substrates on which one or more layers of dielectric material are deposited.
- A very complex dielectric mirror can reflect up to 99.999%, for a narrow range of wavelengths and angles.
- A simpler mirror may reflect 99.9% of the light, but may cover a broader range of wavelengths.

#### Image formation by plane mirror

• A plane mirror will form a virtual image located exactly opposite the real image, as far behind the mirror as the object is from the front of the mirror.

- A "full size" wardrobe mirror should be half your height, no matter where on your body your eyes are placed, and no matter how far away from the mirror you are standing.
- Image of extended object is exactly the same size as the object, but perceived to be at a negative image distance behind mirror.
- Object size = image size => lateral magnification = 1.

28.10.2013	INF-GEO 4310	17	28.10.2013	INF-GEO 4310	18

#### Retro reflectors

- Retro reflectors exist in both specular and diffused modes.
- A corner reflector consists of three mutually perpendicular planes.
- Image produced is inverse of one produced by a single mirror.
- Some applications:
  - simple radar reflectors for ships
  - Laser Range Finders

- Retroreflective or partially retroreflective surfaces
  - Made by depositing a layer of tiny refractive spheres or by creating small pyramid like structures (cube corner reflection).
  - Applications:
    - traffic signs
    - automobile license plates
  - Here, a completely perfect retro reflection is not desired!

#### 28.10.2013

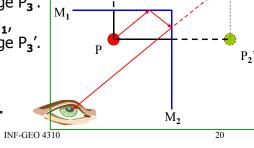

19

## Imaging by retro reflectors

- An image formed by one surface can serve as the object for a second imaging surface.
  - Mirror  $M_1$  forms a virtual image  $P_1'$  of an object point P.
  - Mirror M<sub>2</sub> forms another virtual image P<sub>2</sub>'.

- P<sub>2</sub>' is an object for M<sub>1</sub>, forming virtual image P<sub>3</sub>'.
- This principle will be used extensively.

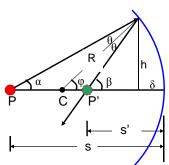

# Sign rules for image formation

- Some general sign rules that will be applicable to all imaging situations that we will encounter later, when both real and virtual images are formed in front of or behind curved surfaces:
- The object distance: When the object is on the same side of the reflecting or refracting surface as the incoming light, the object distance s is positive; otherwise, it is negative.
- The image distance: When the image is on the same side of the reflecting or refracting surface as the outgoing light, the image distance s' is positive; otherwise, it is negative.
- Radius of curvature: When the centre of curvature C is on the same side as the outgoing light, the radius of curvature is positive; otherwise, it is negative.

28.10.2013	INF-GEO 4310	21	28.10.2013

#### **Reflection** by spherical mirror - I

- The concave side of a spherical mirror with radius of curvature R is facing the incident light originating from an object point P on the optical axis.
- A ray from P at an angle a to the axis is reflected by the mirror.
- The angle of incidence and reflection are both  $\theta$ , and the reflected ray crosses the optical axis at an angle  $\beta$ .
- All rays from P will intersect the axis at the same point P', provided that the angle g is small.

INF-GEO 4310

#### 22

#### **Reflection** by spherical mirror - II

- We have the following relations:  $\phi = \alpha + \theta$  and  $\beta = \phi + \theta$ , which implies that  $\mathbf{a} + \mathbf{\beta} = \mathbf{2} \mathbf{\phi}$ .
- The expressions for the tangents of α, β, and  $\phi$  are simply  $tq(a) = h/(s-\delta),$ tq(β) = h/(s'-δ), $tq(\phi) = h/(R-\delta).$

• If the angle  $\alpha$  is small, so are  $\beta$  and  $\phi$ .

Under the paraxial approximation,

a = h/s,  $\beta = h/s'$ ,  $\phi = h/R$ .

 $\delta$  may be neglected compared to (s, s', R). So for small angles we have the following

23

#### Reflection by spherical mirror - III

- Substituting this into  $\mathbf{a} + \mathbf{\beta} = \mathbf{2} \mathbf{\phi}$ we get a general object-image relation for a spherical mirror: -+-=
  - s' R S
- If the radius becomes infinite  $(R = \infty)$ , the mirror becomes plane, and the relation above reduces to s = -s' for a plane reflecting surface.
- If object is far from mirror (s  $\approx \infty$ ), the incoming rays are parallel, and the image will be formed at a distance s' = R/2 from the mirror.

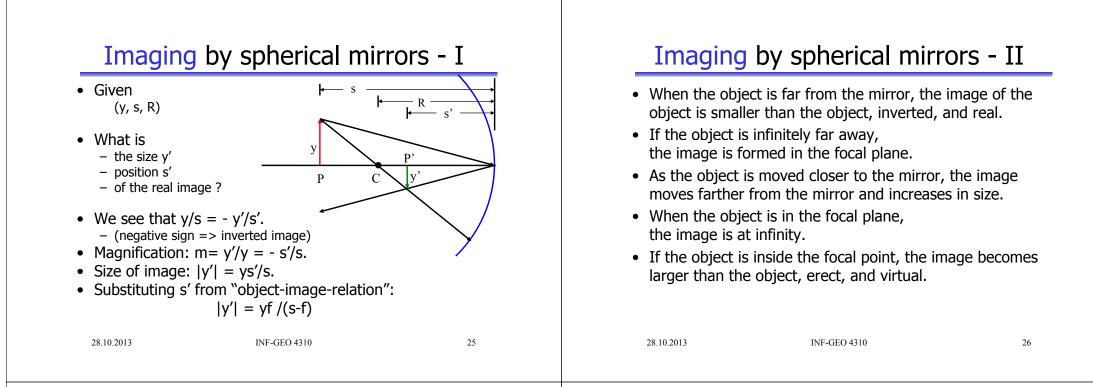

This is the focal length, f.

28.10.2013

approximations:

INF-GEO 4310

#### Optical aberrations, curved mirrors

- Spherical aberration
  - Light striking nearer the periphery focuses closer to the mirror, while light striking near the center focuses farther away. Eliminated by paraboloid mirrors.
- Coma
  - Light entering at an angle to the optical axis, are distorted into tiny "tear drops".
- Astigmatism
  - Rays of light in different planes do not focus at the same distance from the mirror.
- Curvature of field
  - Different parts of a sharp image are formed at different distances from the mirror.
- Distortion
  - Straight lines in the object plane are imaged as curved lines.

#### • Vignetting

- A darkening of the image towards the corners of the field of view.

#### Astronomical telescopes

- Three main types of optical astronomical telescopes:
  - refracting (dioptric) telescopes use an arrangement of lenses.
  - reflecting (catoptric) telescopes use an arrangement of mirrors.
  - catadioptric telescopes use a combination of mirrors and lenses.
- Telescopes increase the apparent angular size of objects, as well as their apparent brightness.
- An eyepiece may be used to view the image.
- In a prime focus design, the image detector sits at the focal point.
- Radio telescopes also often have a prime focus design.

27

#### Optical mirror telescopes - designs

- **Newtonian:** A paraboloid (spherical) primary, and a flat diagonal secondary reflects the light to a focal plane at the side of the top of the telescope tube.
- Cassegrain: A parabolic primary, a convex hyperbolic secondary that reflects the light back through a hole in the primary.
- Ritchey-Chrétien: two hyperbolic mirrors (instead of a parabolic primary).
- Dall-Kirkham: A concave elliptical primary mirror and a convex spherical secondary.
- Schiefspiegler: Tilted mirrors to avoid the secondary casting a shadow on the primary.
- **Maksutov:** A full aperture corrector lens, a spherical primary, and a spherical secondary as an integral part of the corrector lens.
- **Gregorian:** A concave secondary mirror and in this way achieves an upright image.
- Schmidt: A spherical primary mirror, and an aspherical correcting lens.
- **Nasmyth:** Similar to Cassegrain, a third mirror reflects the light to the side and out of the tube.
- **Coudé:** Adding further optics to a Nasmyth design deliver the light to a fixed focus point.

#### 28.10.2013

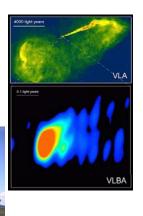

INF-GEO 4310

#### Radio telescopes

• Single dish

Interferometry

28.10.2013

INF-GEO 4310

30

#### Non-optical telescopes

- Single-dish radio telescopes are often made of a conductive wire mesh whose openings are smaller than the reflected wavelength. The shape is often parabolic, and the detector is either placed in prime focus, or a secondary reflector is used.
- Multi-element radio telescopes are constructed from pairs or groups of antennae to synthesize apertures that are similar in size to the separation between the telescopes.
- Large baselines are achieved by utilizing space-based Very Long Baseline Interferometry (VLBI) telescopes such as the Japanese HALCA (Highly Advanced Laboratory for Communications and Astronomy) VSOP (VLBI Space Observatory Program) satellite.
- The VLBI technique is also using radio telescopes on different continents simultaneously.

## **Geometrical Optics: Refraction**

- Snell's law
- The refractive index
  - Sellmeier's equation,
  - Fresnel's equation
  - Critical angle, total internal reflection
- Non-imaging refraction (briefly)
  - Plane-parallel slab
  - Prism
  - Circular dics
    - Two refractions and one reflection primary rainbow

INF-GEO 4310

- Two refractions and two reflections secondary rainbow
- Atmospheric refraction

31

29

28.10.2013

## Snell's law

- Light travels at different velocities in different media.
- This is described by the refraction index of glass, equivalent to ratio of the speed of light in air and glass.
- The result is that the light rays are bent at media interfaces.
- A ray of light passes from air into a plane parallel slab of glass.
- Then Snell's law gives the relation between
  - angle of incidence ( $\theta_1$ ),
  - angle of refraction  $(\bar{\theta}_2)$ ,

28.10.2013

- refraction index of glass (n<sub>2</sub>) and the surrounding medium (n<sub>1</sub>): n<sub>1</sub> sin  $\theta_1 = n_2 \sin \theta_2$ .
- If the index of refraction is given relative to the surrounding medium sin α / sin β = n where α is the angle of incidence and β is the angle of refraction.

# Refractive index

ndex of refra

- The refractive index depends on  $\lambda$  and T.
- Given for 589 nm at 25° C. – (CaII D-line)
- Also weaker dependencies on
  - Pressure
  - Stress
  - Material compositions (dopants, impurities)
- These variations are usually < 1%.

28.10	0.2013	

INF-GEO 4310

34

# The Sellmeier equation

INF-GEO 4310

• An empirical relationship between

the refractive index n

and the wavelength  $\boldsymbol{\lambda}$ 

- for a particular transparent medium.
- The usual form of the Sellmeier equation for glasses is:

 $n(\lambda) = \left[1 + \sum_{i} \frac{B_{i} \lambda^{2}}{\lambda^{2} - C_{i}}\right]^{2}$ 

- Coefficients are usually quoted for  $\boldsymbol{\lambda}$  in micrometers.
- $\lambda$  is the vacuum wavelength; not that in the material itself, which is  $\lambda/n(\lambda)$ .

#### -----

28.10.2013

35

33

#### **Reflection and refraction**

 When light moves from a medium with refractive index n<sub>1</sub> into a second medium with refractive index n<sub>2</sub>, both reflection and refraction of the light may occur.

-BK7 -silica -CaF2

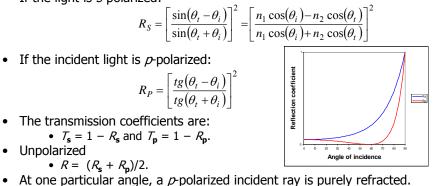

800 1000 1200

wavelength (nm)

- The reflection angle is equal to the incidence angle  $(\theta_r = \theta_i)$ .
- The angle of refraction,  $\theta_t$ , is given by Snell's law.

#### Fresnel's equation – non-magnetic materials

- May be used to calculate the fraction R of the intensity of incident light that is reflected from the interface.
- If the light is *s*-polarized:

- Brewster's angle,  $\approx 56^{\circ}$  for a glass medium in air or vacuum.

28.10.2013

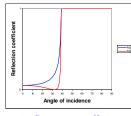

Unpolarized

INF-GEO 4310

#### Critical angle, total internal reflection

- When  $n_1 > n_2$ , all light is reflected above an incidence angle known as the *critical angle*, and  $R_s = R_p = 1$ .
- This phenomenon is known as *total internal reflection*.
- The critical angle is approximately 41° for glass in air.
- Important application: Reflective optical prisms
- When  $\theta_i \approx \theta_t \approx 0$ , we have:

$$R = R_S = R_P = \left[\frac{n_1 - n_2}{n_1 + n_2}\right]^2$$
$$T = T_S = T_P = 1 - R = \frac{4n_1n_2}{(n_1 + n_2)^2}$$

Reflection coefficients from glass to air.

```
28.10.2013
```

INF-GEO 4310

38

# **Applied refraction: Prisms**

- Optical prisms can be sub-divided into two categories:
- Reflective prisms
  - Utilizing total internal reflection in order to
    - Alter direction of the light beam
    - Shift the beam by a certain amount in a given direction
    - Rotate and/or flip the image
- Dispersive prisms
  - Disperse a broad band (white light) beam into a spectrum

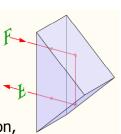

## Reflective prisms

- Reflective prisms utilize internal reflection at surfaces.
- Entering and exiting prism: to avoid light dispersion, light beam has to be orthogonal to a prism surface.
- Inside prism: if beam hits a surface at an angle greater than the critical angle, there is total internal reflection.
- All of the light is reflected in accordance with the law of reflection (angle of incidence = angle of reflection).
- Thus, reflective prisms may be used to alter the direction of light beams, to offset the beam, and to rotate or flip images.

37

# Single right-angle triangular prism

- Two modes of operation:
- 1. Direction of the beam is altered by 90°, and the image is reflected left-to-right, as in an ordinary plane mirror.
- Beam exits in the opposite direction and is offset from the entering beam. The image is rotated 180°, and by two reflections the left-to-right relation is not changed.

41

• We are guaranteed total internal reflection, since the angles of incidence is always 45°.

28.10.2013		

INF-GEO 4310

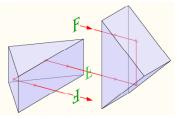

#### Combinations of right-triangular prisms - II

- Alternative configuration:
  - "Porro-Abbe prism"
- Exits beam offset in horizontal direction.
  - Image is rotated 180°,
  - handedness is unchanged.
- Used in small telescopes to re-orient inverted image.
- Even more common in binoculars where they both erect the image and provide a longer, folded distance between the objective lens system and the eyepieces.

# F

#### Combinations of right-triangular prisms - I

- The simplest configuration:
  - "Porro prism"
- Normal incidence and exit.
- Beam will traverse both prisms through four reflections.

- The net effect is a beam parallel to but displaced from its original direction, both horizontally and vertically.
- Image is rotated 180°, and given the even number of reflections, the handedness of the image is unchanged.

INF-GEO 4310

#### 42

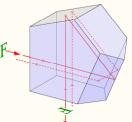

#### Combinations of right-triangular prisms - III

- A roof ("Amici") prism is a combination for two right-angled triangular prisms.
  - A simple right-angled prism with a right-angled "roof" prism on its longest side.
- The roof prism flips the image laterally, while the handedness of the image is unchanged.
- Used to deviate a beam of light by 90° and simultaneously inverting the image, e.g., in the eyepiece of a telescope.

# Pentaprism - I

- Beam enters orthogonal to one of the two orthogonal rectangular faces of a (90°, 112.5°, 112,5°, 112.5°) pentaprism.
- The prism allows the transmission of an image through a 90° angle without inverting it.
- There is no total internal reflection, so the reflecting faces have to be coated to obtain mirror surfaces.
- The two orthogonal transmitting faces are often coated with an antireflection coating to reduce reflections.

- Pentaprism II
- A roofed pentaprism is a combination of an ordinary pentaprism and a right-angle triangular prism.

- The triangular prism substitutes one of the mirror faces of the ordinary pentaprism.
   Thus, the handedness of the image is changed.
- This construction is commonly used in the viewfinder of single-lens reflex (SLR) cameras.

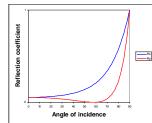

28.10.2013	INF-GEO 4310	45	28.10.2013	INF-GEO 4310	46

## Dispersive prisms

- A light beam striking a face of a prism is partly reflected and partly refracted.
- Amount of light reflected is given by Fresnel's equations.
- Direction of reflected beam is given by  $\theta_i = \theta_r$ .
- Light striking boundary between two media *at angle* θ<sub>i</sub> proceeds into the new medium at a *different* angle, θ<sub>r</sub>, given by Snell's law: sin θ<sub>i</sub> / sin θ<sub>r</sub> = n.
- Since the refractive index **n** varies with wavelength, light of different colors is refracted differently.
- Blue light will be bent more than red light.

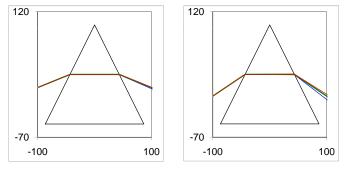

#### Dispersion in triangular prism

- The most widely-known type of optical prism.
- Dispersion occurs because
  - the angle of <u>refraction</u> is dependent on the <u>refractive index</u>, which in turn is dependent on the <u>wavelength</u>.
- The top angle of the prism is often chosen so that light rays hit the surface at <u>Brewster angle (</u>≈ 56°), so <u>reflection</u> losses are minimized.

# Dispersion in triangular prism

• BK7 glass has a relatively small dispersion, while SF10 (dense flint glass) have a much stronger dispersion.

28.10.2013

INF-GEO 4310

#### Grazing refraction

When light travels from a high to a low refractive index medium, the ray is bent away from the normal.

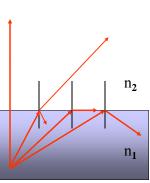

At the critical angle of incidence, given by

 $\theta_{crit} = \arcsin(n_2/n_1),$ 

- $n_1 \sin \theta_1 = n_2 \sin \theta_2$  $n_2$
- If θ < θ<sub>crit</sub>, the ray will split.
   Part of the ray will reflect off the boundary, and some will refract as it passes through.

the refracted ray will be grazing the surface.

• If  $\theta > \theta_{crit}$ , all of the ray reflects from the boundary. None passes through.

50

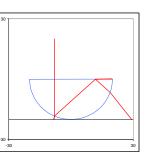

```
28.10.2013
```

28.10.2013

INF-GEO 4310

## A water bowl example

- Given a semi-circular bowl of water.
- A light-ray from a 632.8 nm laser enters perpendicular to the surface 4/10 of the radius from the centre of the bowl.
- We want to obtain grazing refraction and total internal reflection.
- At 25°C, how much do you have to raise the refractive index of the water by increasing the salinity?
  - » (See http://www.luxpop.com/)

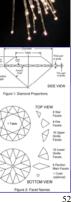

49

## Optical fibers and diamonds

- In large core diameter optical fibers, confinement is based on total internal reflection.
- Diamond has an extremely high refractive index
  - low critical angle about 24.4°
  - light is much more likely to be internally reflected within a diamond than in glass – critical angle about 41.5°.

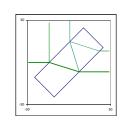

INF-GEO 4310

 The "brilliant cut" is designed to achieve high total reflection of light entering the diamond, and high dispersion of the reflected light.

#### Refraction in plane-parallel slab

• When the beam exits the glass slab, the angle of incidence equals  $\beta$ , the relative index of refraction is 1/n, and the exit angle  $\phi$  is given by n sin  $\beta$ = sin  $\phi$ .

- The net effect is that the plane parallel glass slab has caused a parallel displacement of the light beam.
- The displacement, d, given relative to the thickness of the slab, is

 $d = \sin \alpha \left( 1 - \frac{\cos \alpha}{\sqrt{n^2 - \sin^2 \alpha}} \right)$ 

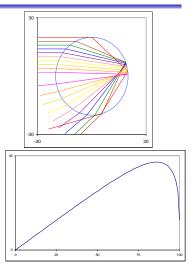

53

28.10.2013

INF-GEO 4310

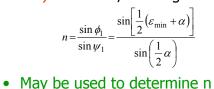

#### Two refractions and one reflection by a circular disc

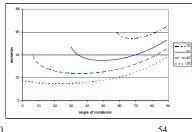

- Parallel rays of light enter a circular disc, and are refracted.
- A small fraction (4%) of the refracted light is reflected from the back of the disc.
- Refracted again upon exiting the disc.
- Exit rays "pile up" at a maximum exit angle.
- For the refraction index of water,  $\phi_{\textrm{M}}\approx42^{o}.$

# Refraction by prism

- Let *α* be the top angle of a symmetric triangular prism.
- A minimum value of the angle of deviation, ε, is obtained when the passage of light through the prism is *symmetrical*, and is given by

28.10.2013

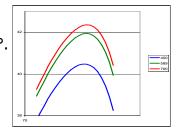

when  $\alpha$  is known and  $\epsilon_{min}$  is measured.

INF-GEO 4310

#### Primary rainbow

- The "piling up" of exit angles implies a bright disc having angular radius  $\phi_{\mathbf{M}}$  centered on the point in the sky opposite the light source.
- Disc is brightest around its rim.
- No light reaches us from  $\phi > \phi_{\textbf{M}}$
- $\phi_{\mathbf{M}}$  depends on wavelength.
- Visual color spectrum from violet to red is spread out over 40.8° – 42.5°.
- Distance does not matter
  - the rainbow is a collection of rays
  - not located at any point in space.

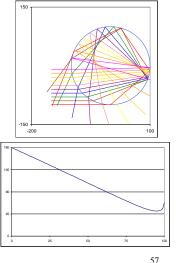

55

#### Two refractions and two reflections by a circular disc

- Parallel rays of light enter a circular disc, and are refracted.
- A small fraction (0.16%) of the refracted light is reflected twice inside the disc.
- Refracted again upon exiting the disc.
- Exit rays "pile up" at a *minimum exit angle*.
- For the refraction index of water,  $\phi_{M2} \approx 52^{\circ}$ .

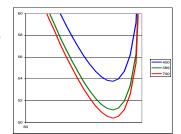

#### Secondary rainbow

INF-GEO 4310

- The "piling up" of exit angles gives a darker "hole" centered on the point in the sky opposite the light source.
- The angular radius of this "hole" is φ<sub>M2</sub>, or about 52°.
- $\phi_{M2}$  depends on wavelength.
- The order of the colors is reversed.
- Secondary bow wider than primary.
- Bright "disc" of primary bow, and dark "hole" of secondary, results in dark "Alexander-band" between bows.

28.10.2013

58

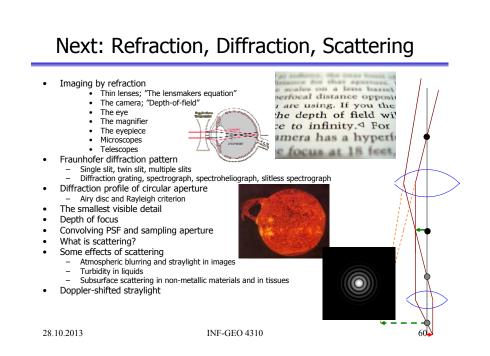

#### Atmospheric refraction

**INF-GEO 4310** 

- Variation in air density as a function of altitude causes light or other electromagnetic waves to deviate from a straight line during a passage through the atmosphere.
- The atmospheric refraction causes astronomical objects to appear higher in the sky:
  - zero in the zenith

28.10.2013

- less than 1' at 45° altitude
- only 5' at 10° altitude
- 29' half a degree (one solar diameter) above horizon
- 34' at the horizon.
- Setting / rising sun is *flattened* by about 1/6 of apparent diameter. Thermal inversion layers may create additional phenomena.
- Values above are for 10 °C and 1003 mbar.
  - Add 1% to the refraction for every 3° C colder, subtract if hotter.
     Add 1% for every 9 mbar higher pressure, subtract if lower.
  - Add 1% for every 9 mbar higher pressure, subtract if lower.
- Atmospheric refraction near the ground can produce *mirages*.
- Light passing through layers and bubbles of air having different densities, will continuously alter direction, causes stars to appear as *twinkling*.

28.10.2013
