A.20.T

- a. Define potential temperature (θ).

Assume that the air is dry. What is the criterion for static stability of the atmosphere, given by θ ?

- b. Draw the two points A and B on a sonde diagram, with temperatures $T_A = 10^\circ\text{C}$, $T_B = 0^\circ\text{C}$ and pressures $p_A = 1000\text{hPa}$ and $p_B = 700\text{hPa}$. We assume the lapse rate is constant between A and B.

Is the layer between A and B stable?

- c. If an air parcel in the middle of this layer is displaced from its position, it will start oscillating. What do we call the frequency of these oscillations? Find the period of the oscillations in this case.

- d. Assume the lapse rate between 700 hPa and 400 hPa is close to dry adiabatic, and that the relative humidity is 95 % at A and 80 % at B. Find the level of free convection (LFC) for A and B. Comment on the likeliness that the conditional instability will be released in each case.

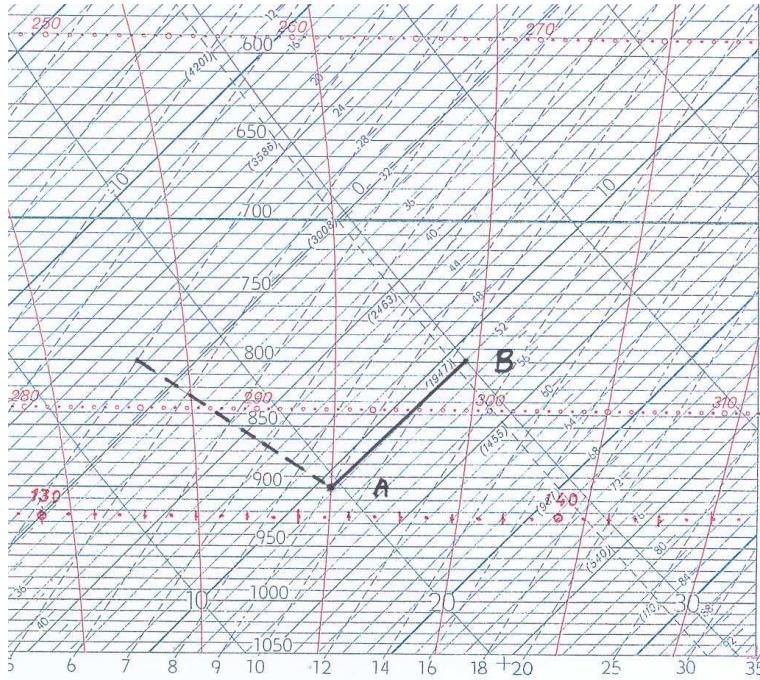

Figure 1: Temperatur T (heltrukken linje) og duggpunkt T_d (stiplet) for en sonde.

A.74.T

Eksamens GEF2200 08-1

Deler av en sondeoppstigning er vist i Figur 1, der temperaturen T og dugpunktstemperaturen T_d er gjengitt for et lag A-B.

- Hvordan er stabiliteten i laget A-B?
- Laget A-B heves 100hPa. Er laget mer eller mindre stabilt nå? Begrund svaret kort.
- Laget heves 100hPa til. Hvordan er stabiliteten i laget A-B nå? Begrund svaret kort.
