

# Path planning for autonomous vehicles

Solveig Bruvoll, FFI

May 19 2016

# Mobile robots/autonomous vehicles vs. manipulators

- Manipulators
  - Fixed position
  - Limited workspace
- Mobile robots
  - Position changes
  - Environment changes and may be «unlimited»
  - Uncertainty in position and environment

# Autonomous vehicles

- Where am I?
- What should I do?
- How should I do it?

FOTO: FFI

# Autonomous vehicles

- Where am I?
  - What should I do?
  - How should I do it?
- 
- Where am I?
  - Where am I going?
  - How should I get there?

# Autonomous vehicles consist of

- Sensors
  - What is in my surroundings?
- Payload
  - What I will use to complete my task
- Equipment for movement
  - How I will move while performing my task
- Tools for reasoning
  - Artificial intelligence

# Two approaches

- How should the vehicle be constructed to execute these tasks?
- How should we use this vehicle to execute these tasks?

# Two approaches

- How should the vehicle be constructed to execute these tasks?
- How should we use this vehicle to execute these tasks?

Should we use this vehicle?

Should we execute this task?

**Robots provide new possibilities!**

The vehicles consist of:

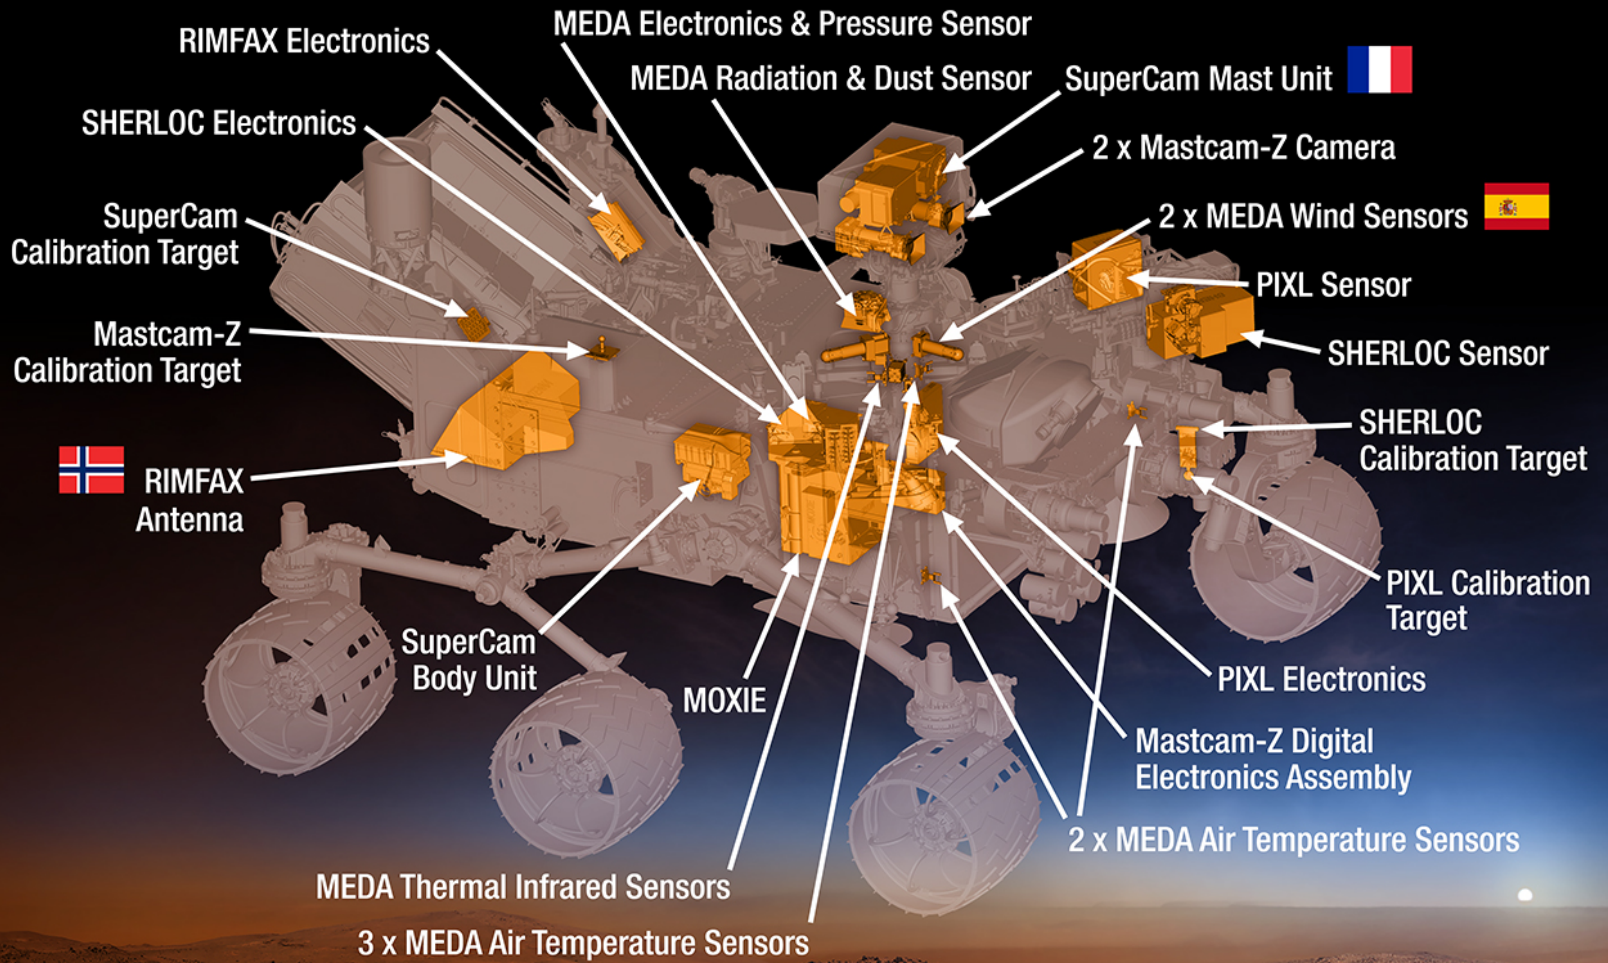

- Sensors
- Payload
- Equipment for movement
- Tools for reasoning

# Sensors

- Depends on the type of vehicle
- Internal and external sensors
- Passive and active sensors
- State monitoring
  - Positioning
  - «Health»
- Perceiving the environment
  - Avoid obstacles
  - Information gathering (of task relevant information)

# Mars 2020 Rover

# Environment model

- Continuous or discrete
- Layers of data
- Discrete hierarchical model to achieve suitable precision

# State monitoring

- Sensor functionality
- Position
- Fuel
- Weather
- System failures

Photo: US Air Force

- Alert: Change behavior and/or plan to avoid failure.
  - Complete the task in a different way
  - Abort mission

# Autonomous task planning

- How to best use my payload to execute this task in the current environment given my current state?
- Usually involves movement for autonomous vehicles.

# Distributed autonomy

- Am I cooperating with anyone?
  - Equal relationship or master/slave?
  - Same types of vehicles or different properties?
- Communication
  - With other autonomous units
  - With a control station or human

# Path planning

- Positioning and movement of the vehicle in the environment.
- Path planning dependent on task and situation is important.
- Relation to cooperating units.
- Path planning is often done hierarchically.
  - Discrete routes on high levels.
  - Detailed short distance routes can be continuous.

# Why do we need a tool for path planning?

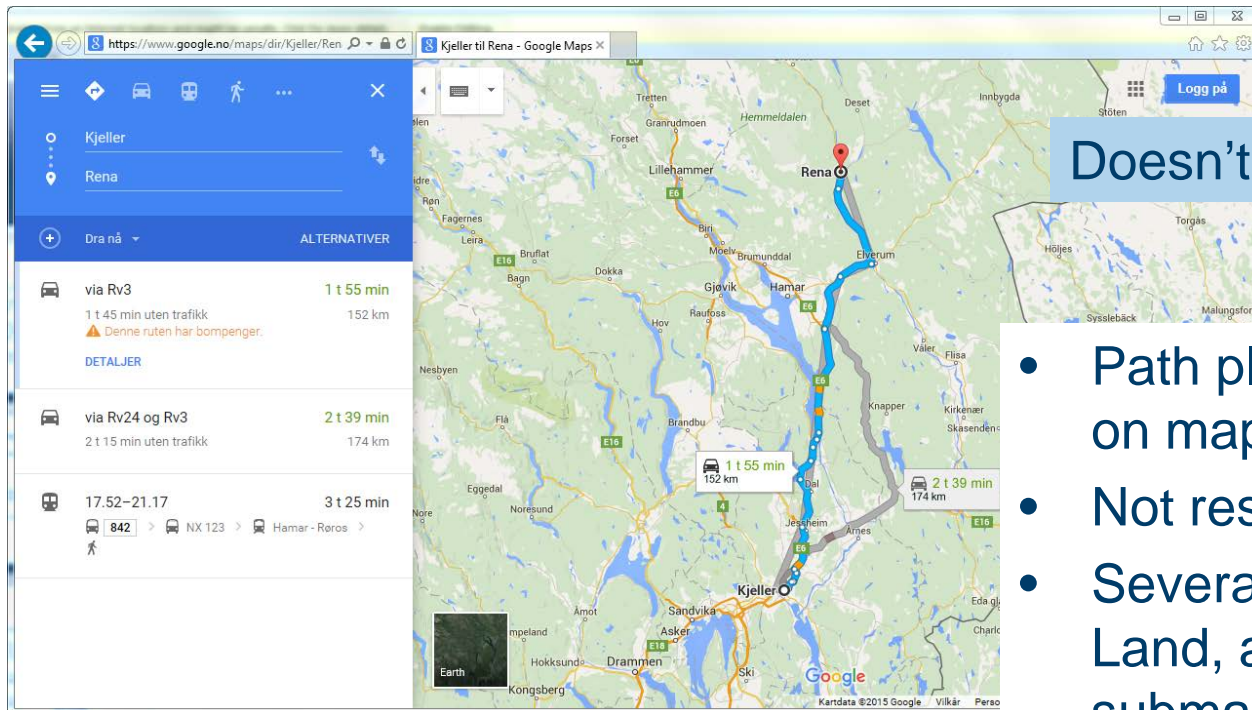

The screenshot shows a Google Maps interface with a route from Kjeller to Rena. The left sidebar lists three alternatives:

Route	Distance	Time
via Rv3	152 km	1 t 55 min
via Rv24 og Rv3	174 km	2 t 39 min
17.52-21.17		3 t 25 min

A blue callout box with the text "Doesn't it exist?" is overlaid on the map, pointing to the route options.

# Why do we need a tool for path planning?

- Path planning not only based on maps.
- Not restricted to roads.
- Several types of entities: Land, air, surface, and submarines.
- Aspects as threat and task specific needs.

# Example terrain

Screenshot from VR-Forces, MÅK

# Automatic path planning

Screenshot from VR-Forces, MÄK

- A graph that represents the possible movements through the terrain.
- Weights for the edges in the graph representing the relative accessibility of each edge.
- An algorithm for determining the shortest path through the weighted graph.
  - Often A\*, a generalization of Dijkstra.

# Examples of path planning methods

- Continuous methods
- Potential fields
- Fast marching methods
- Graph based
  - Visibility graph
  - Tile graph
  - Voronoy diagrams
  - Random/adaptive sampling
  - *Dijkstra, A\*, D\*..*

Which method should be used when?

Which properties influence this choice?

# Graph generation

Screenshot from VR-Forces, MÅK

- Areas with accessible terrain types are used to create a navigation mesh.
- A graph is constructed based on the mesh.
- The same graph will be used for several types of vehicles.
  - Only extremely sloped areas are accounted for at this stage.

# Graph generation

Screenshot from VR-Forces, MÅK

# Weighted graph

# Path planning algorithm

## Dijkstra

- Find the optimal path from a start node to an end node.

## A\*

- Find the (probably) optimal path from a start node to an end node.
- Introduces a heuristic function to speed up the search.
- The heuristic function determines whether an optimal solution is guaranteed.
- Implementations often terminate the first time the end node is visited.

# How does a path depend on the situation?

1. The situation around the entity:
  - Terrain
  - Enemies
  - ...
2. Which task the entity is performing

# How does a path depend on the situation?

1. The situation around the entity:

- Terrain
- Enemies
- ...

Aspects

2. Which task the entity is performing

Priority

# Priority of aspects

1. Time
2. Accessibility
3. Concealment
4. Cover
5. Threat

The relative priority of the aspects depends on the task the entity is performing.

Each aspect is assigned a number from 1 to 10, where 10 represents the highest priority.

The aspect weights are combined into a new situation dependent weight.

# Our work includes

- Programming
- Optimization
- Mathematics
- Artificial intelligence
- Information security
