Evolutionary robotics

Kyrre Glette

Today: Evolutionary robotics

- Why evolutionary robotics
- Basics of evolutionary optimization
  - INF3490 will discuss algorithms in detail
- Illustrating examples
  - ROBIN in-house robotic platforms and experiments
- Research challenges
  - Reality gap

Example: Henriette

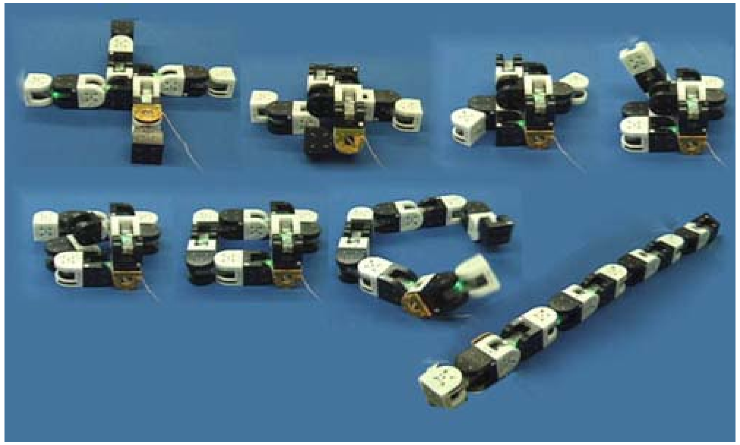
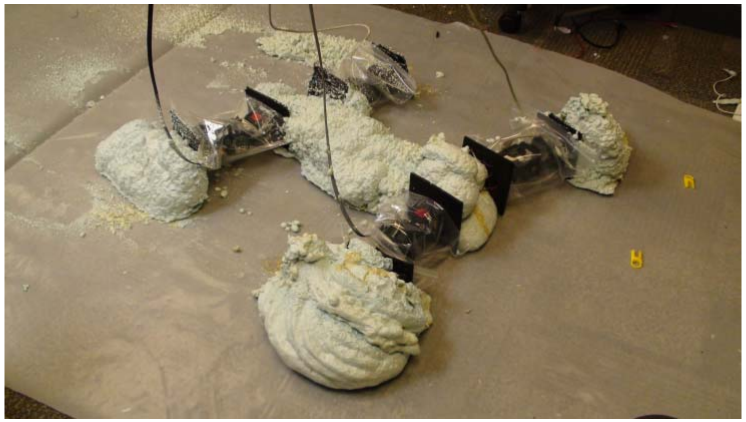
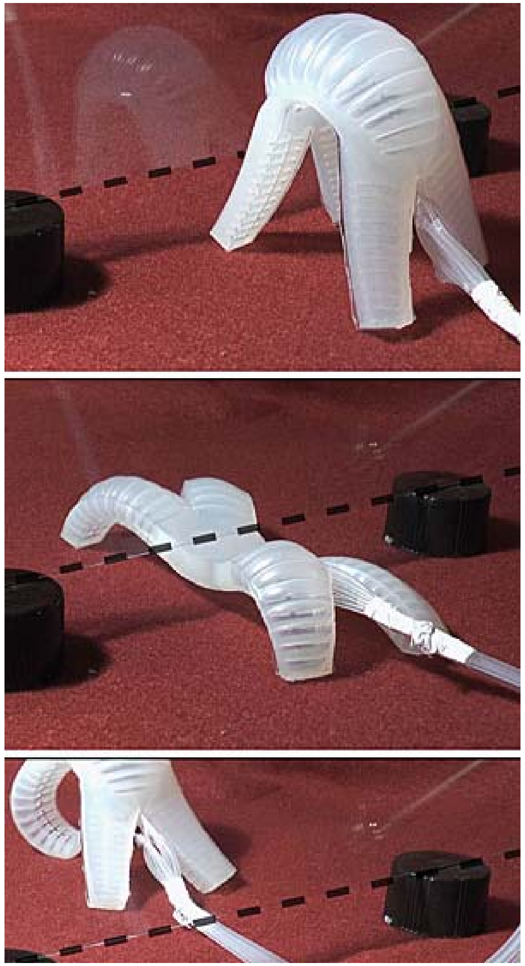
Future robots & scenarios





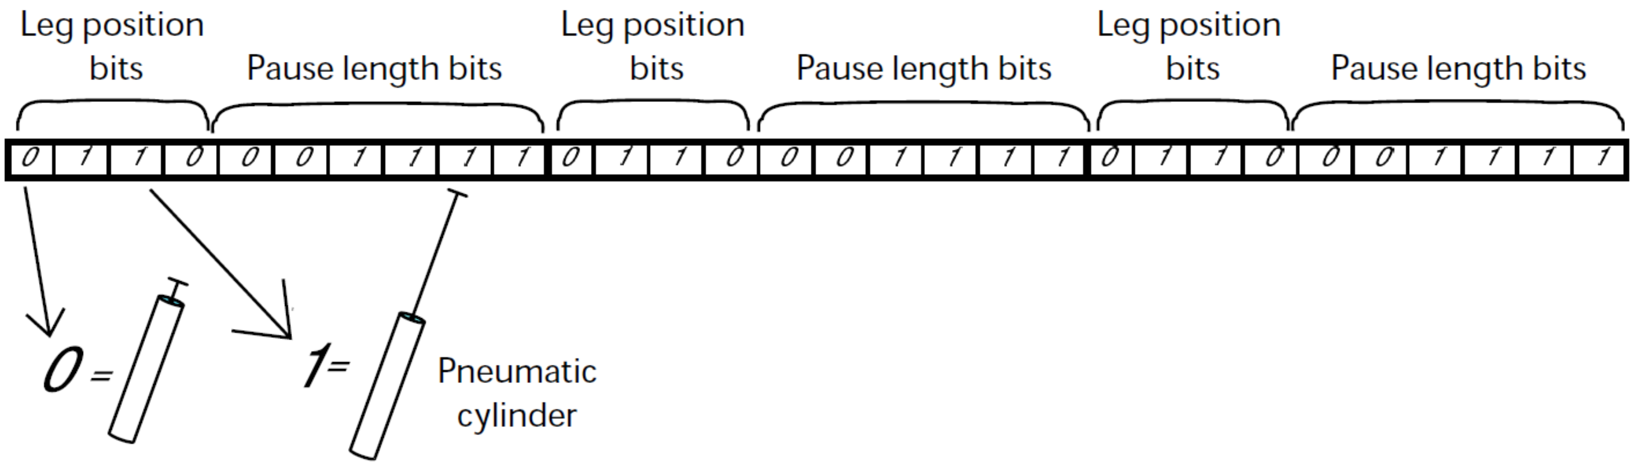


Why evolutionary robotics?

- Adaptation to changes in environment or robot
  - Robot may break or deteriorate
  - Environment may change unexpectedly
- Optimizing for efficiency
  - Energy, speed weight, actuators
- Unconventional, complex designs
  - New materials and actuators make it more challenging with conventional design approaches

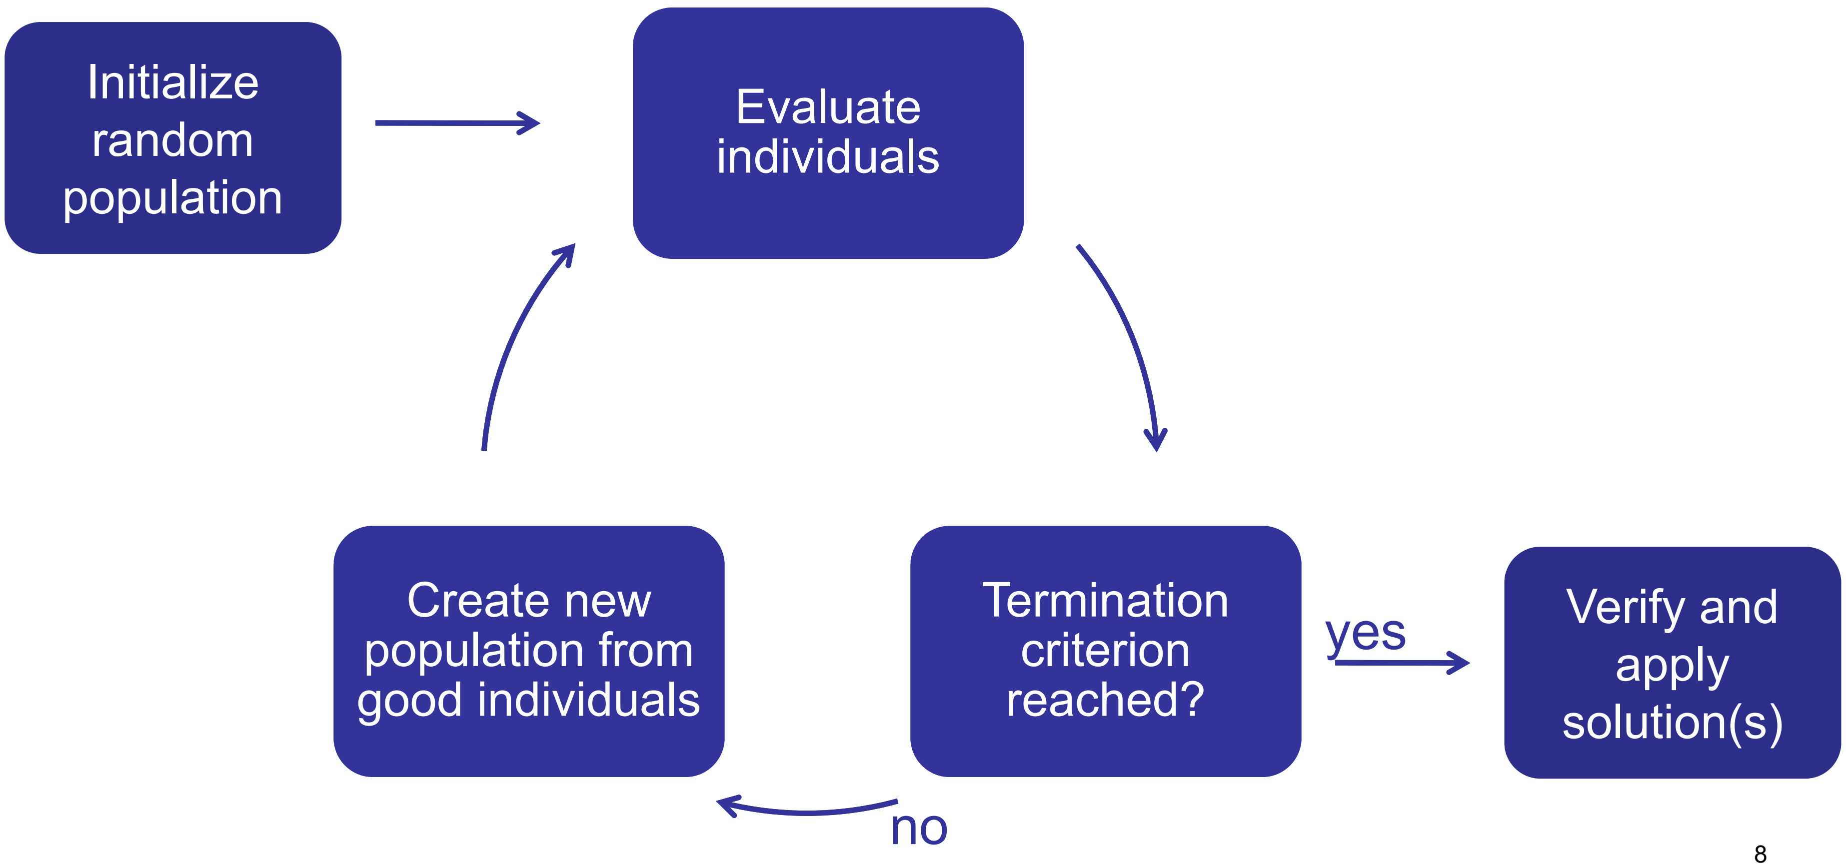
Adaptation, optimization, exploration

Henriette: Parameterized control



- Walking pattern coded into bit strings.
- 3 “states” consisting of leg configuration and pause length
- An evolutionary algorithm was used to evolve the leg configurations and the pause length.
- For each leg configuration, 4 bits denote the position of 4 actuators, 6 bits denote the length of the pause.
- Total bit string / *genome* length: 30 bits

Evolutionary Algorithm (EA)



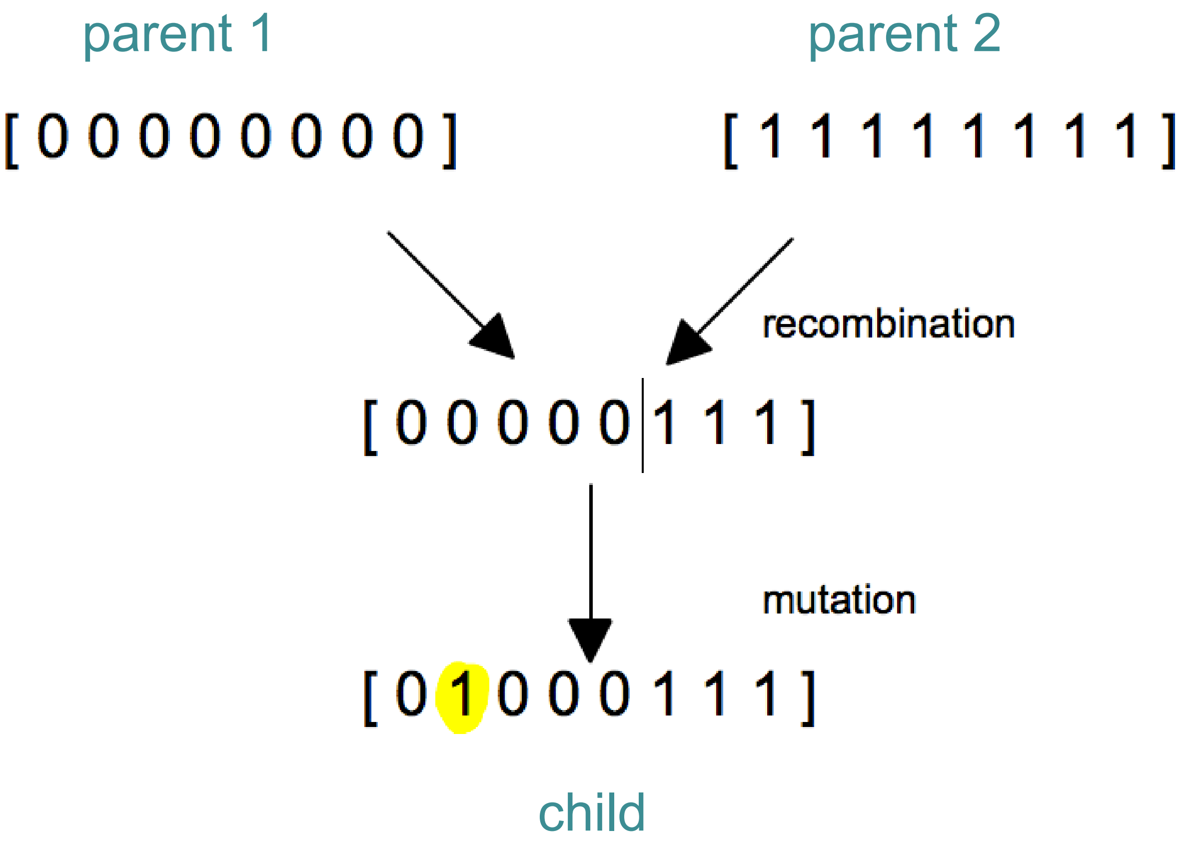
Evolutionary mechanisms

- Selection
  - Good / fit individuals have a higher chance of reproducing
- Inheritance
  - Properties from parents are transferred to offspring
- Variation
  - Changes in the genome adjust the behavior of the offspring, sometimes to the better

Selection

- Each *individual* in a population is evaluated and assigned a *fitness* value, ie. a measure of how a solution performs a given task
  - Example: The forward speed of a robot
  - Henriette: measured by the angular difference from the rotation encoder over 3 repetitions of the sequence
- The probability of an individual being selected for reproduction is proportional to its fitness value (randomness is present)

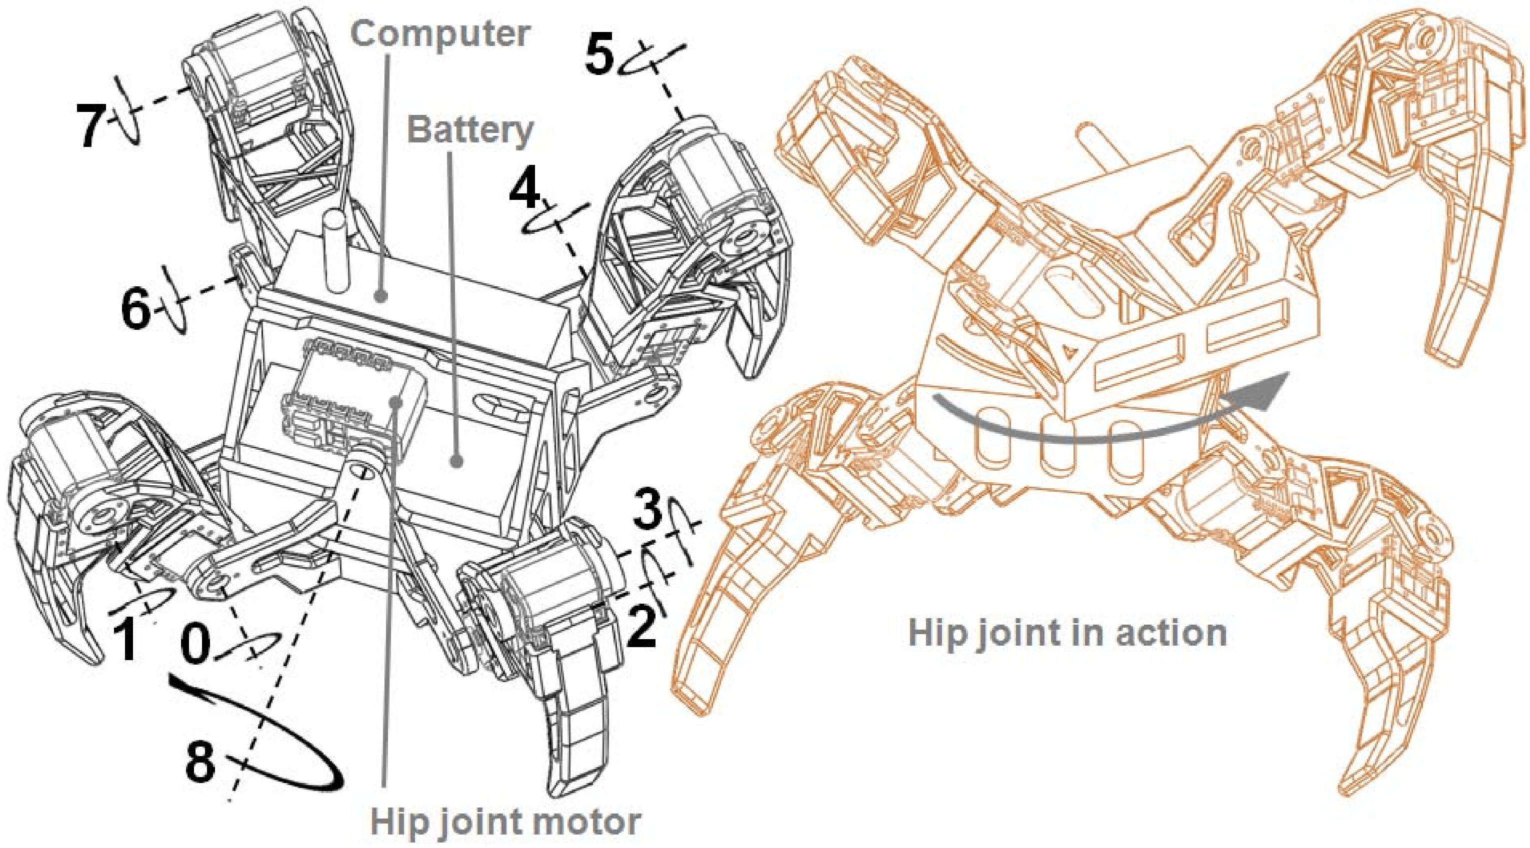
Inheritance + variation



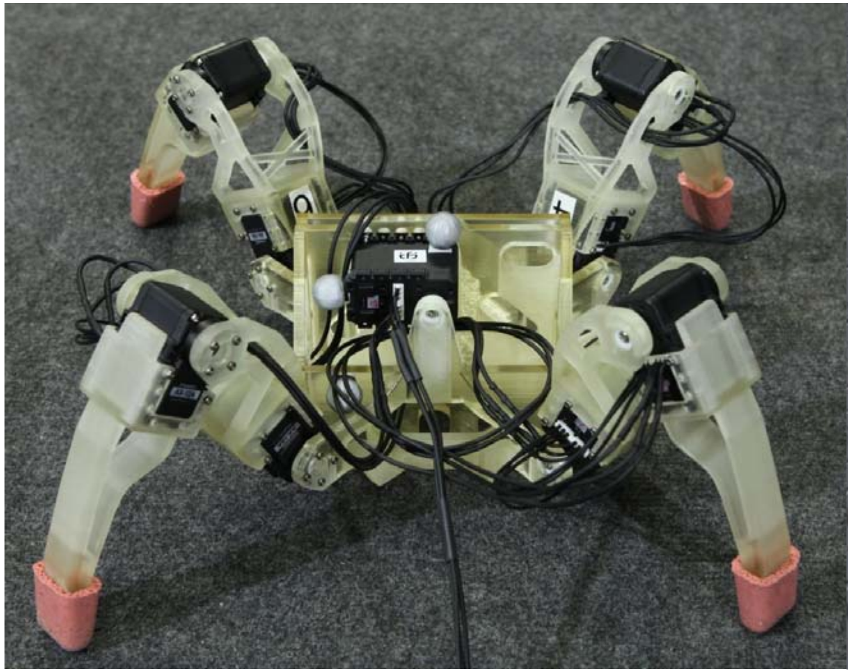
Simulation

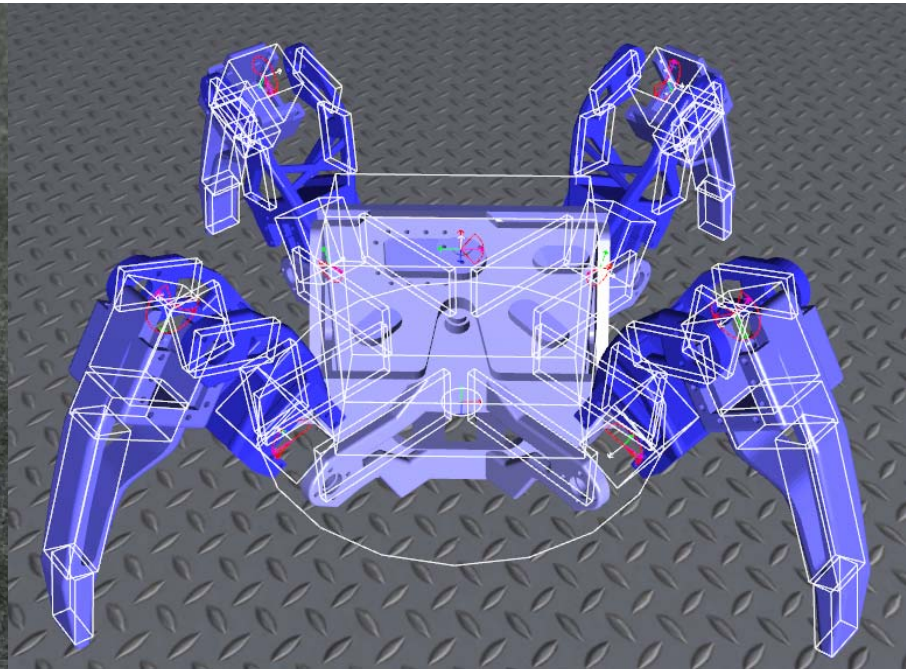
- Evolution on a real robot is impractical
  - Time consuming
  - Requires supervision: can get stuck, fall over
  - Mechanical wear
- Simulation should help
  - Allows automated evaluation
  - Can be much faster
    - especially with parallel computation

Example: Quadratot



Quadratot: Hardware and model





3D printed parts

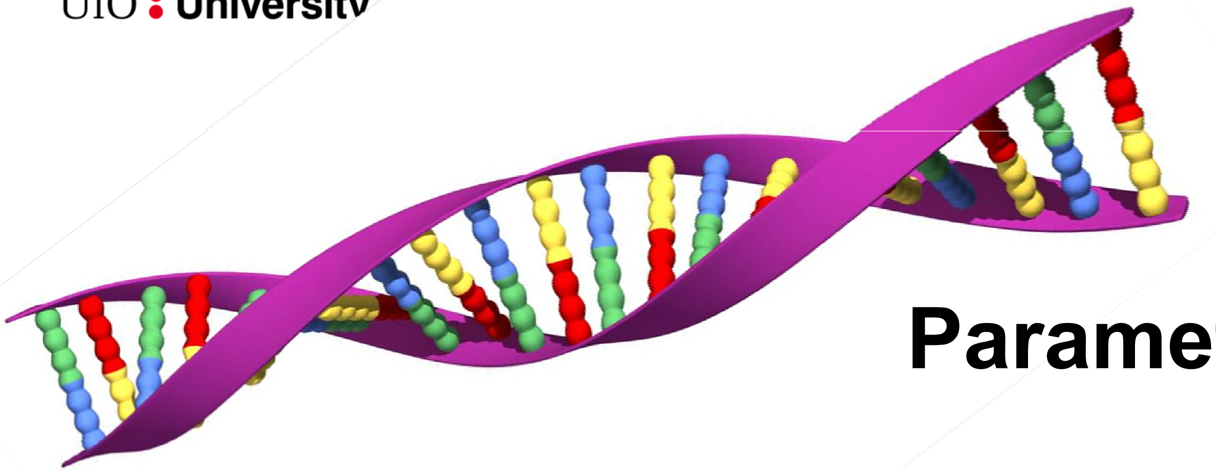
AX12/18 servos

Silicone rubber socks

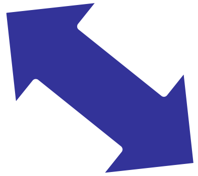
NVIDIA PhysX

Revolute motor joints

Rigid bodies (boxes)

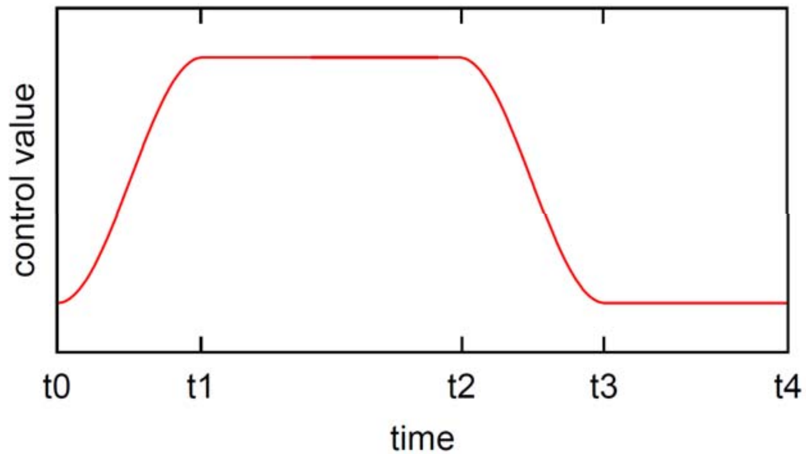


Quadratot: Parameterized control (mapping)



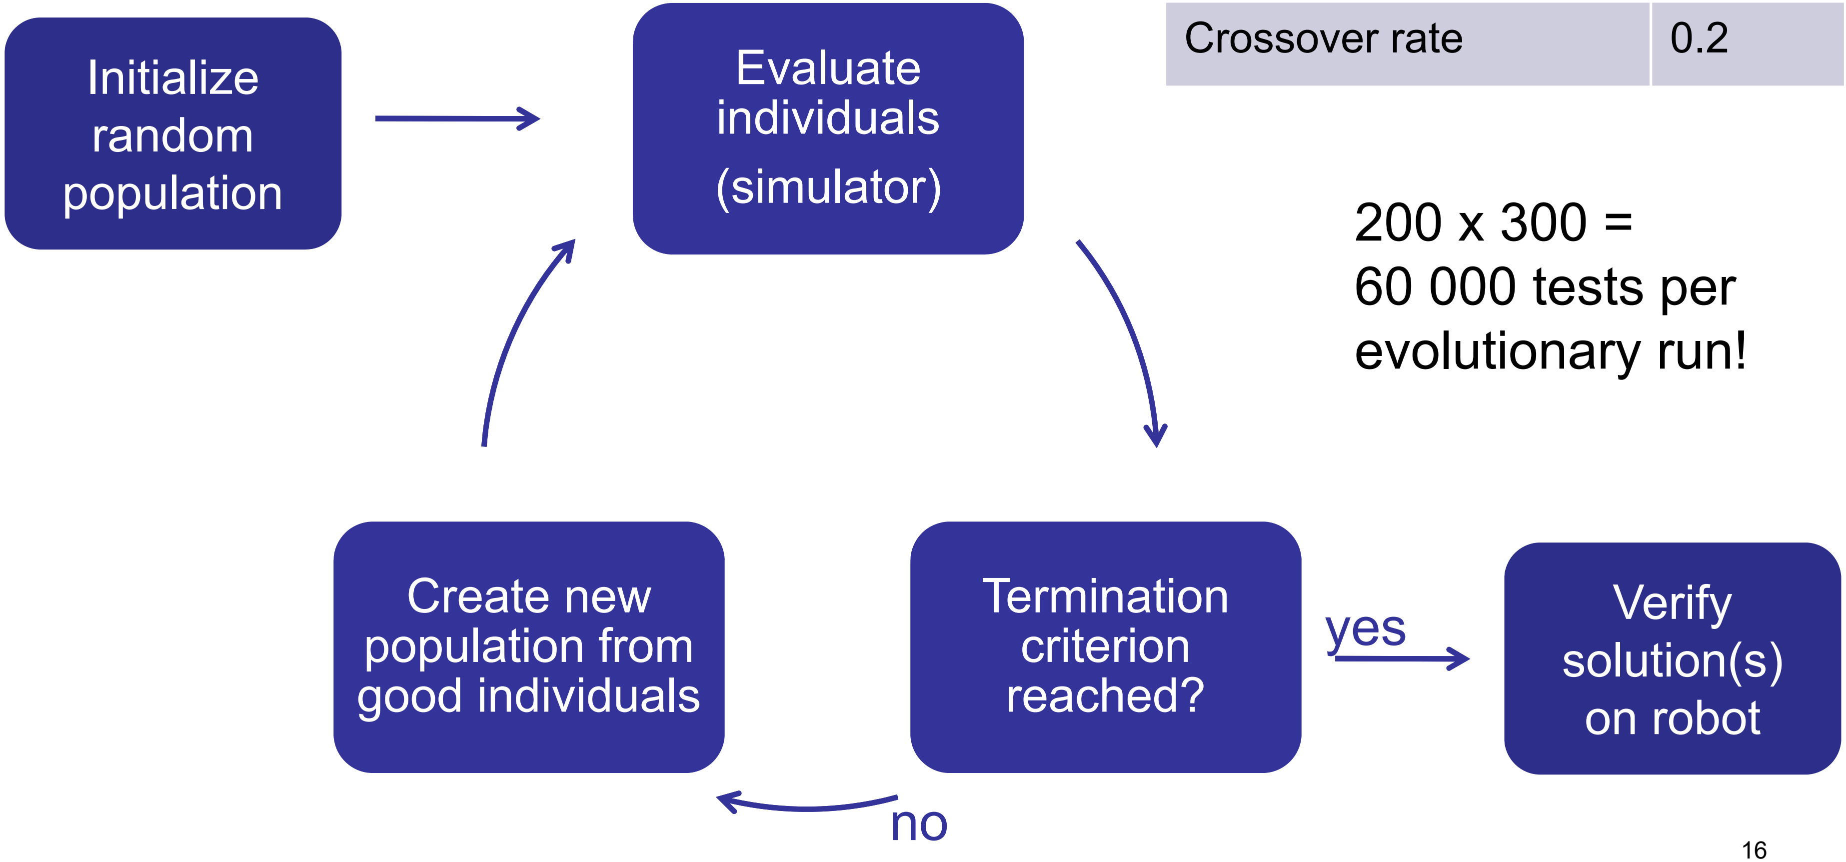
For each joint:

- Curve shape parameters (4)
- Phase
- Amplitude
- Center angle



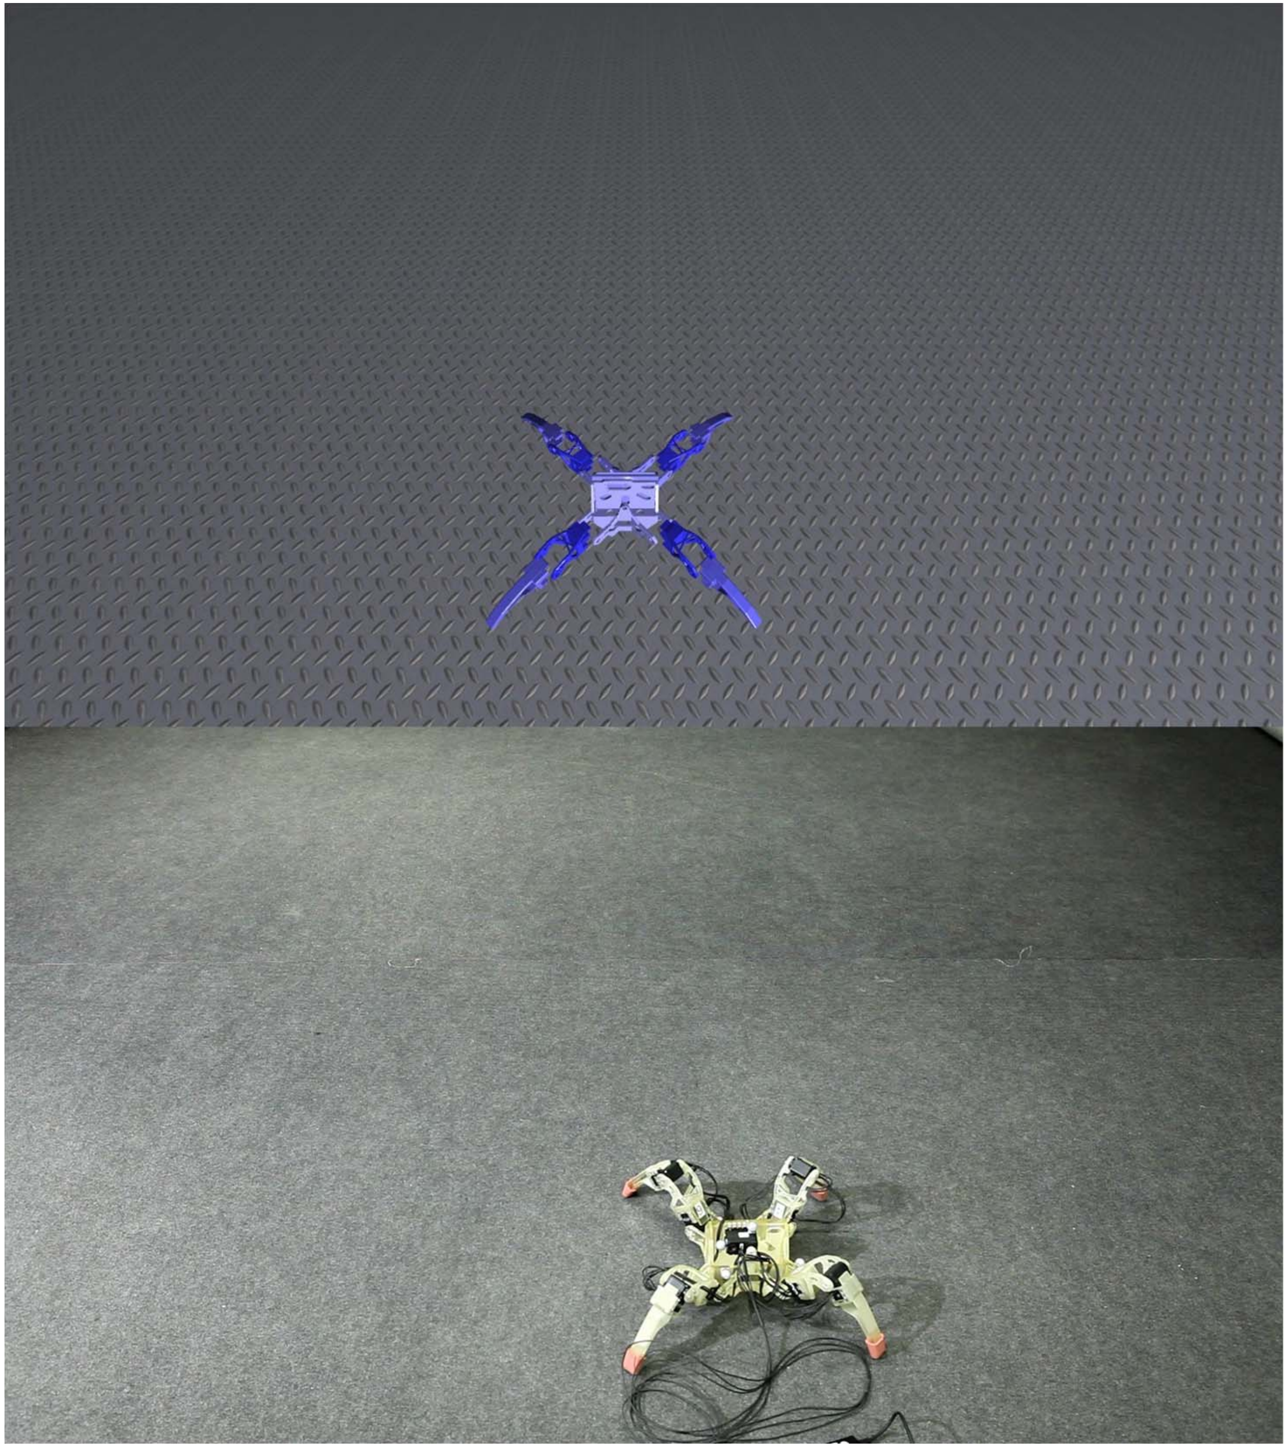
Quadratot: Genetic algorithm (GA)

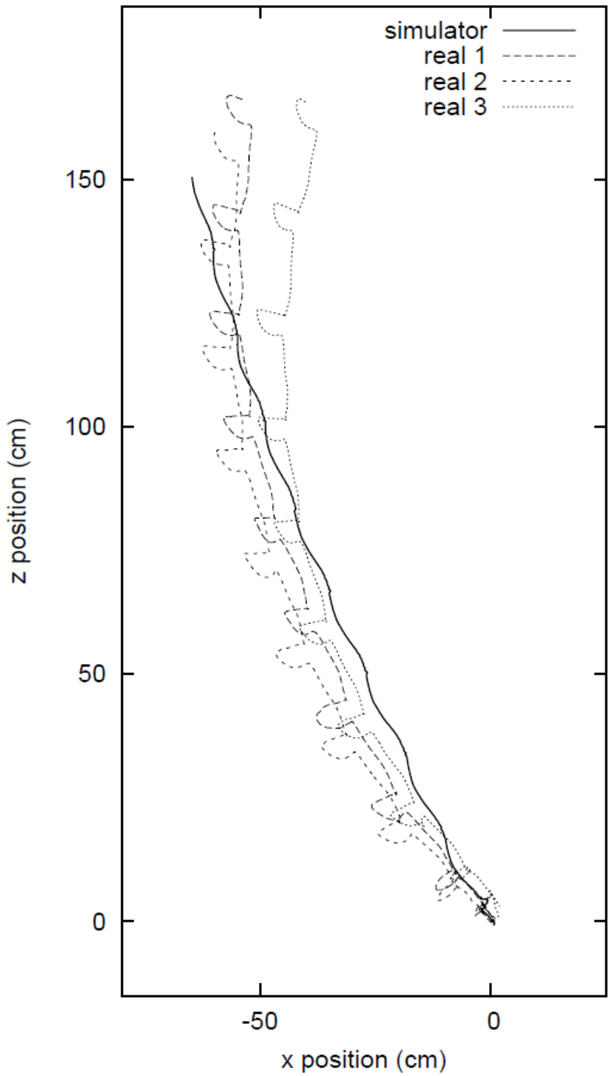
Genome length	314 bits
Population size	200
Number of generations	300
Mutation rate	1/314
Crossover rate	0.2



200 x 300 =
60 000 tests per
evolutionary run!

Quadratot: Evolved gait

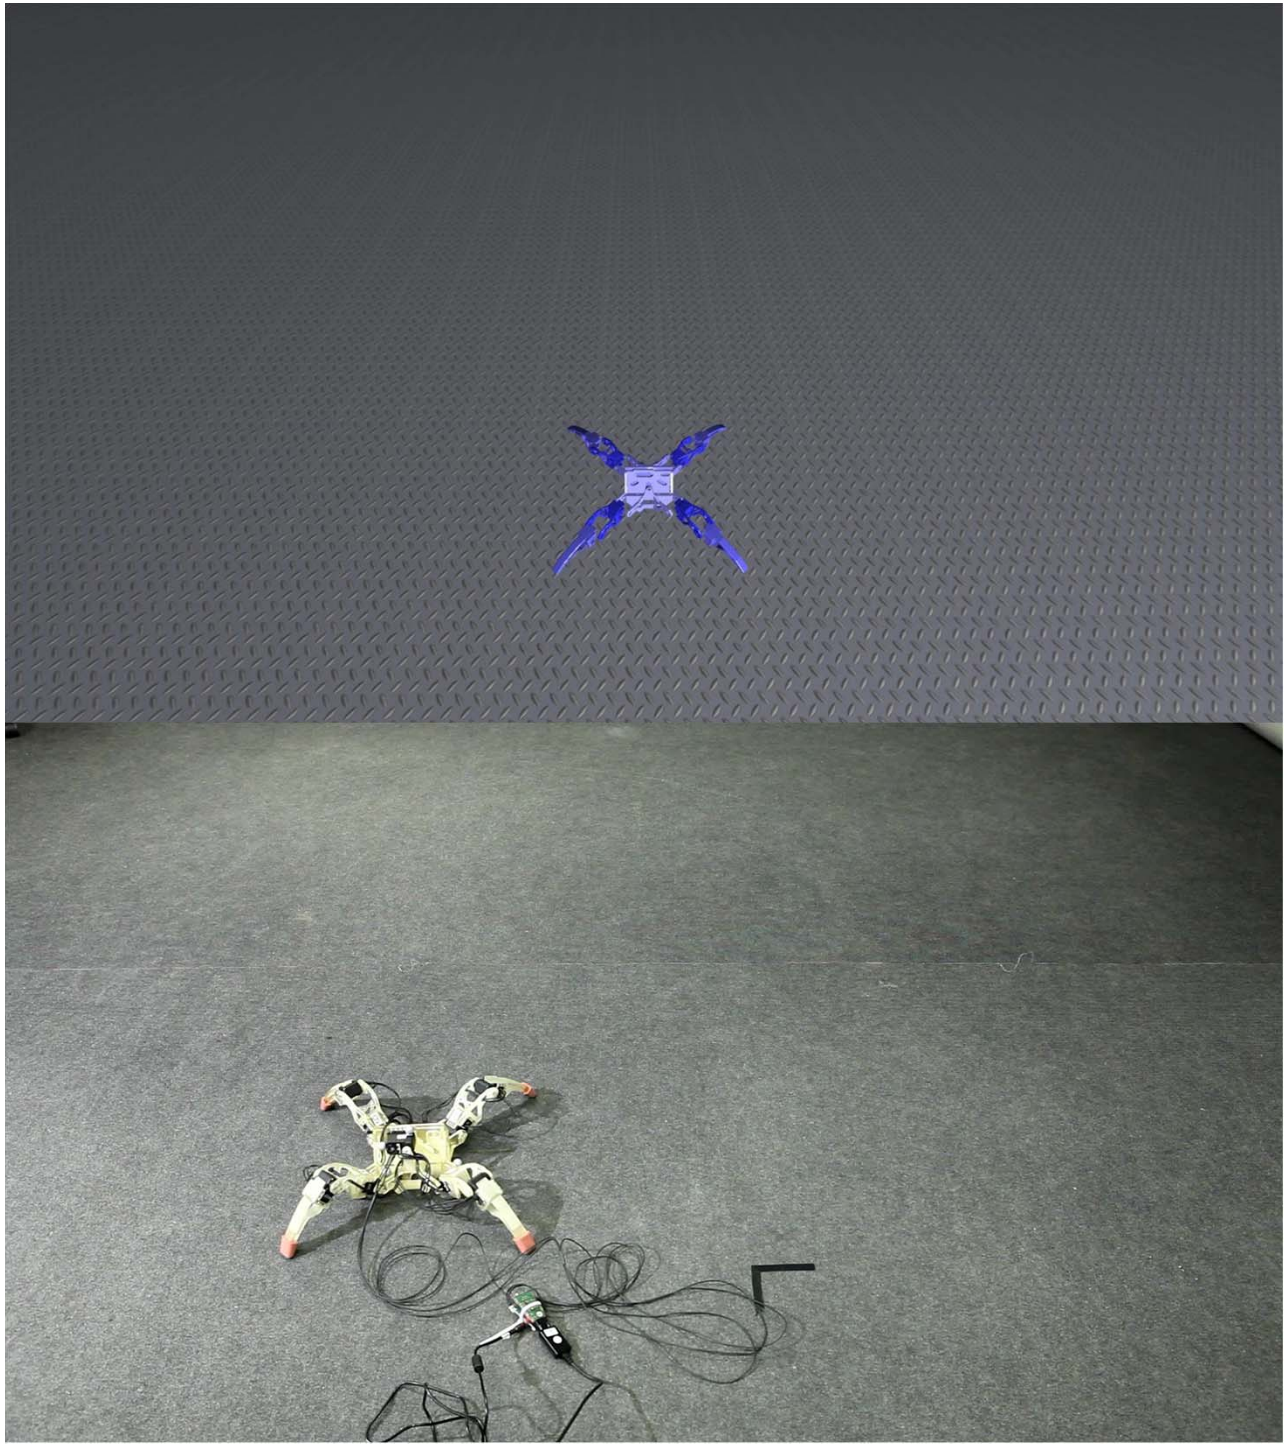




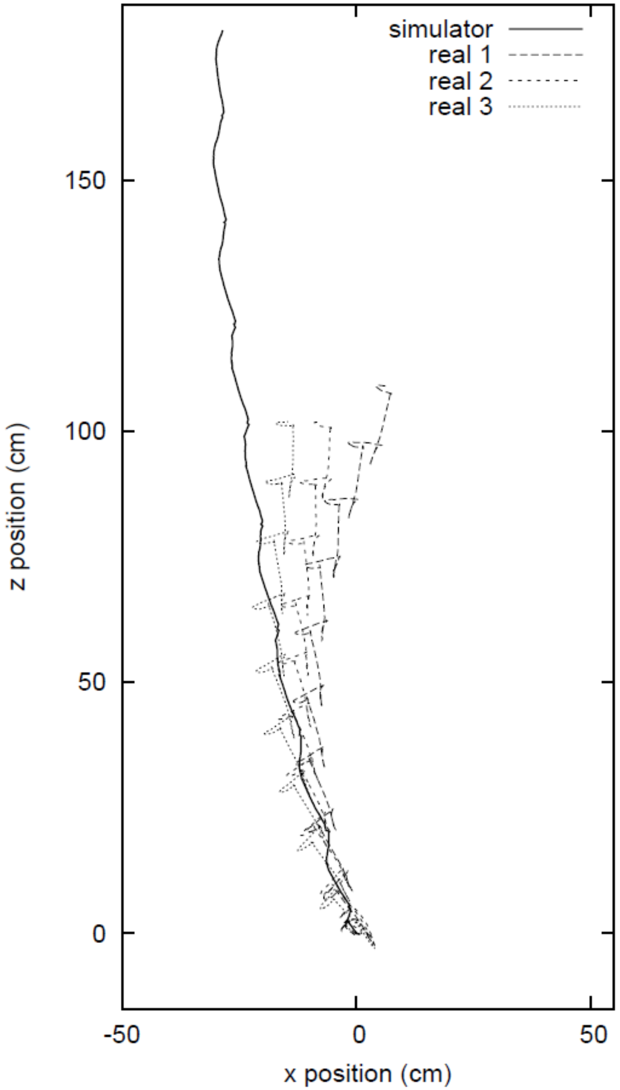
Challenge: Reality gap

- A simulator cannot capture all aspects of reality
- Evolved solutions may exploit features of the simulator not present in reality

→ The solutions evolved in simulation behave differently when applied to the real robot!



Quadratot: Reality gap



How to deal with the reality gap?

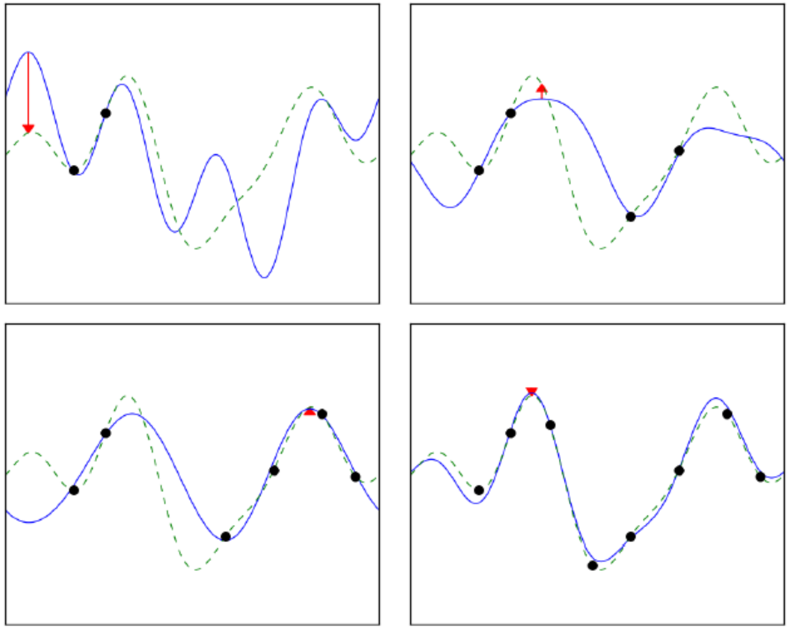
- Ideas?

How to deal with the reality gap

1. Increase simulation fidelity
   - Manually: do more precise measurements, increase solver accuracy
   - Automatically: measure deviation simulation-reality, auto-tune simulator for smaller deviation
2. Do not allow for solutions using badly simulated behaviour
   - Manually: E.g. Encourage slow, static movements, add noise
   - Automatically: Avoid solution types that transfer poorly
3. Online learning after deployment on real robot
   - Can use more evolution, reinforcement learning, or other method

1. Automatic simulator tuning

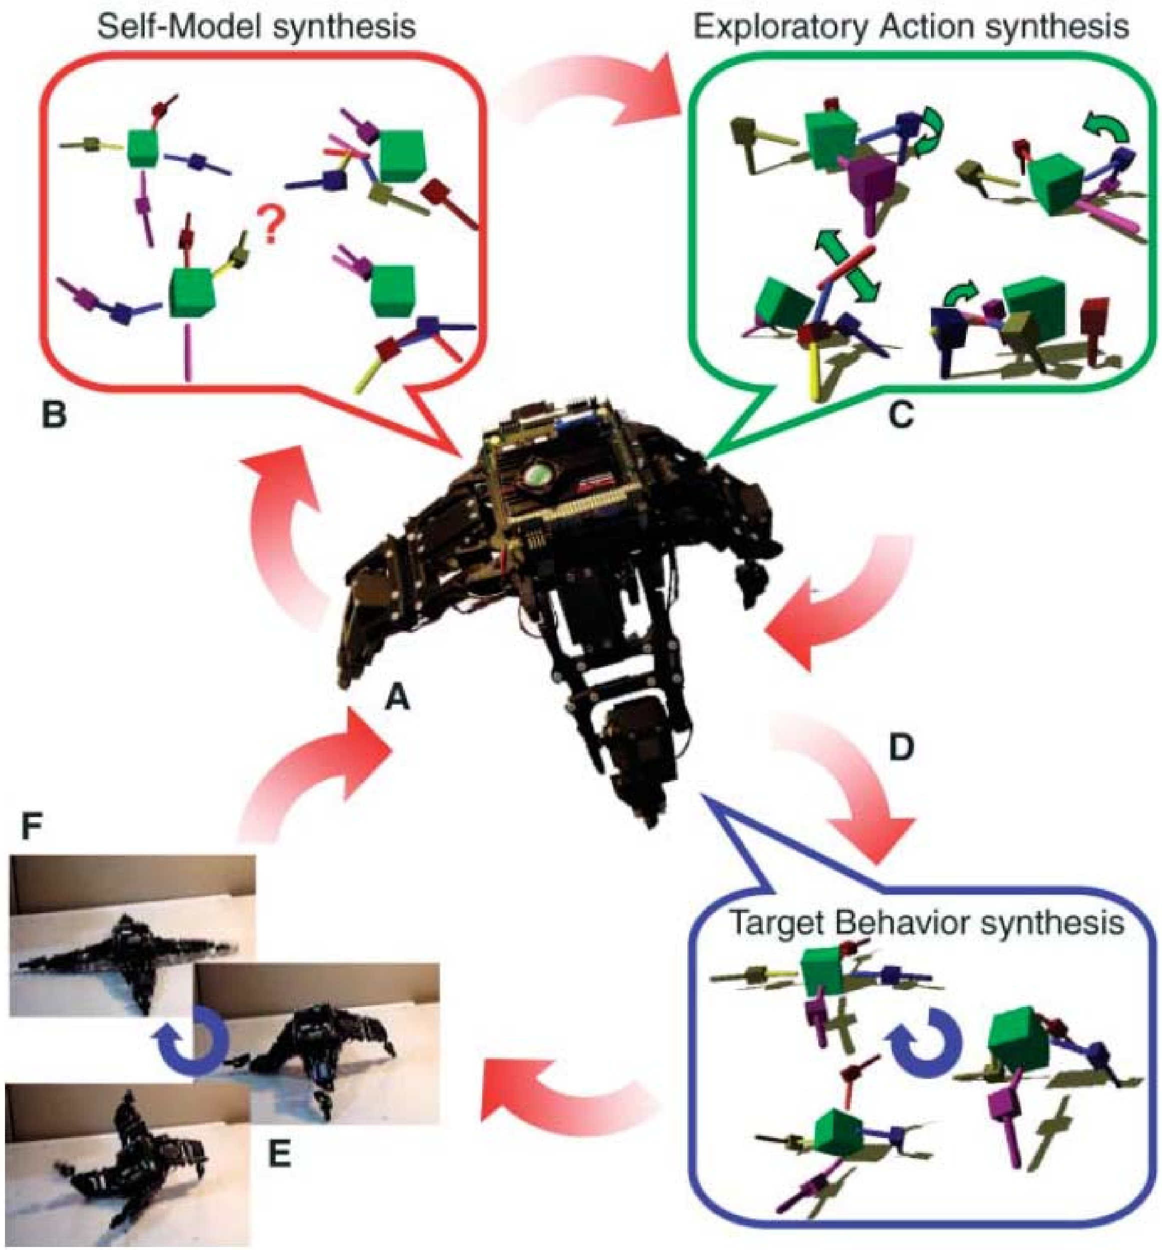
- Sample from real world
  - Test selected solutions on real robot
- Tune (evolve) simulator to fit all samples
- Evolve new solutions using tuned simulator



Self-modeling robot (Cornell U.)

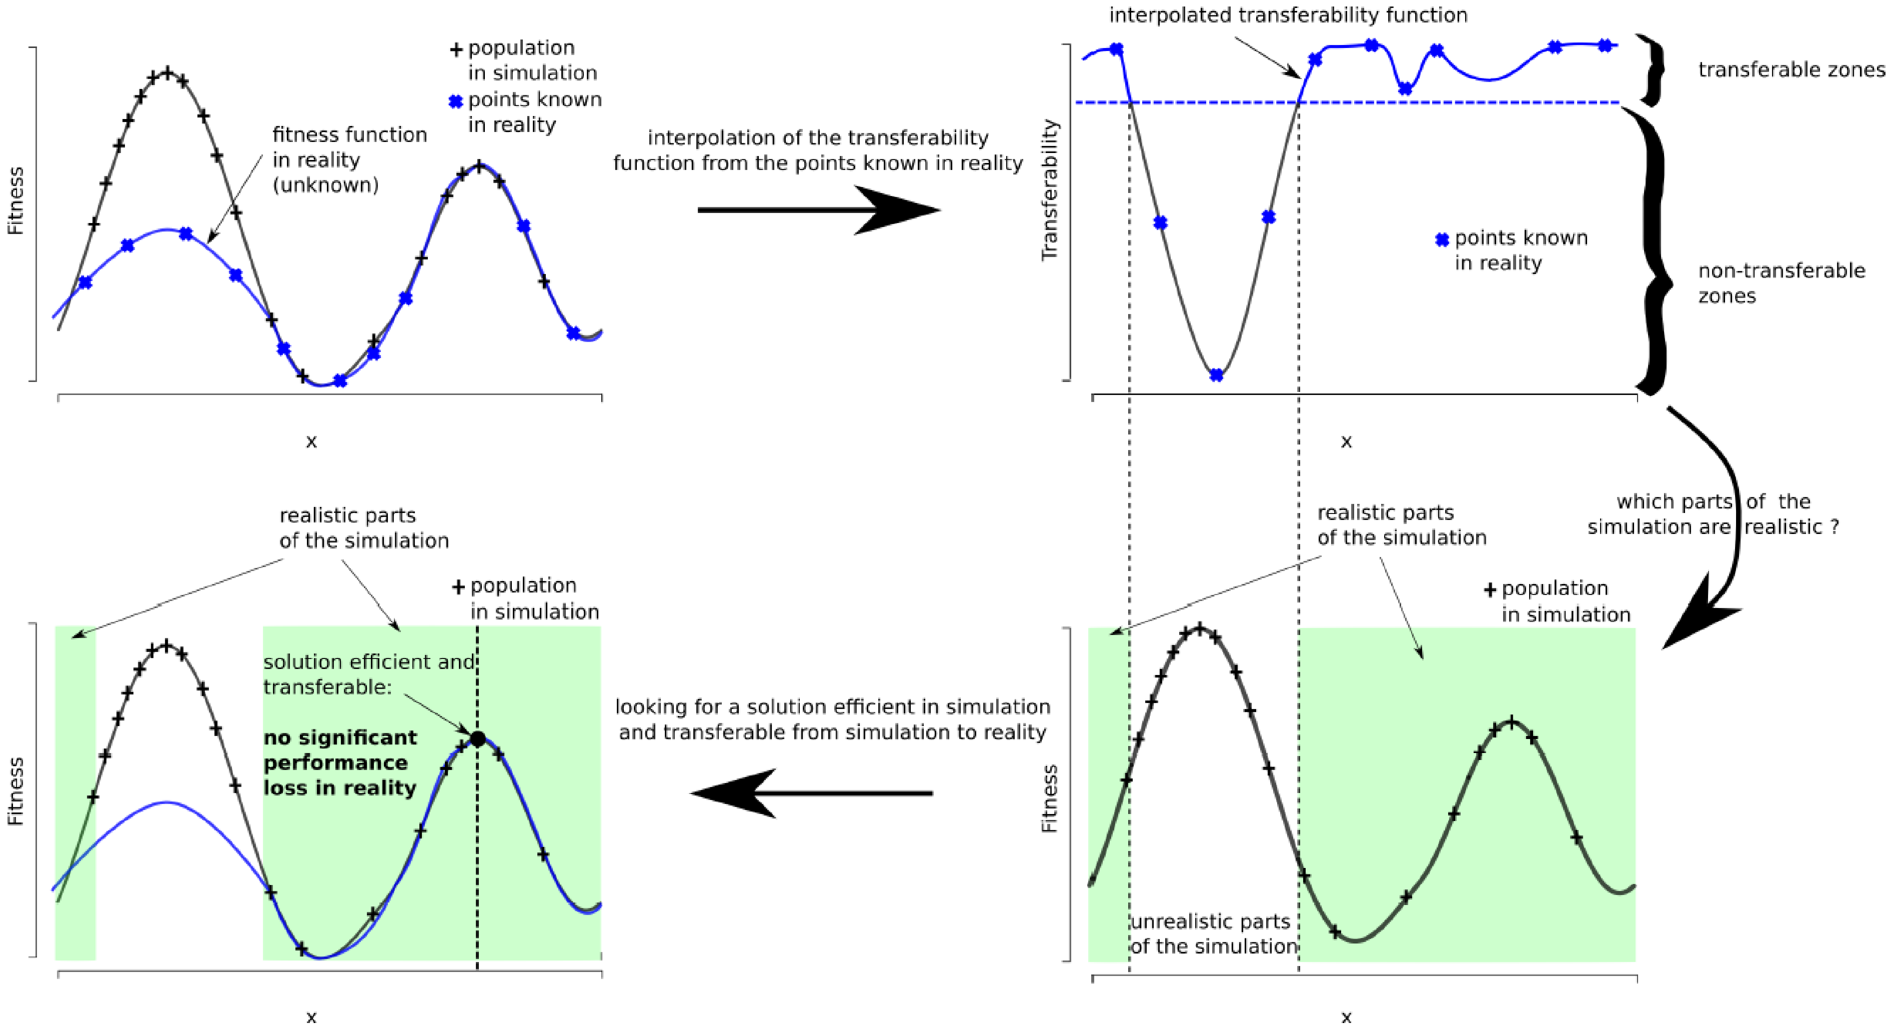
- Creates self-model through exploratory actions
- Uses evolution to search for walking pattern using self-model
- If the robot is broken, a new self-model is constructed

http://youtu.be/3HFAB7frZWM



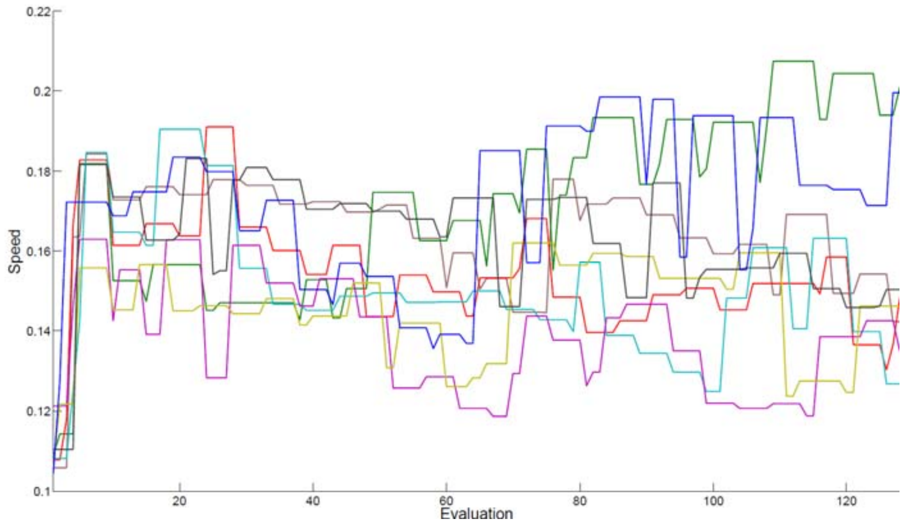
http://youtu.be/qDPbXvADyio
http://youtu.be/MSwdmC0dZ74

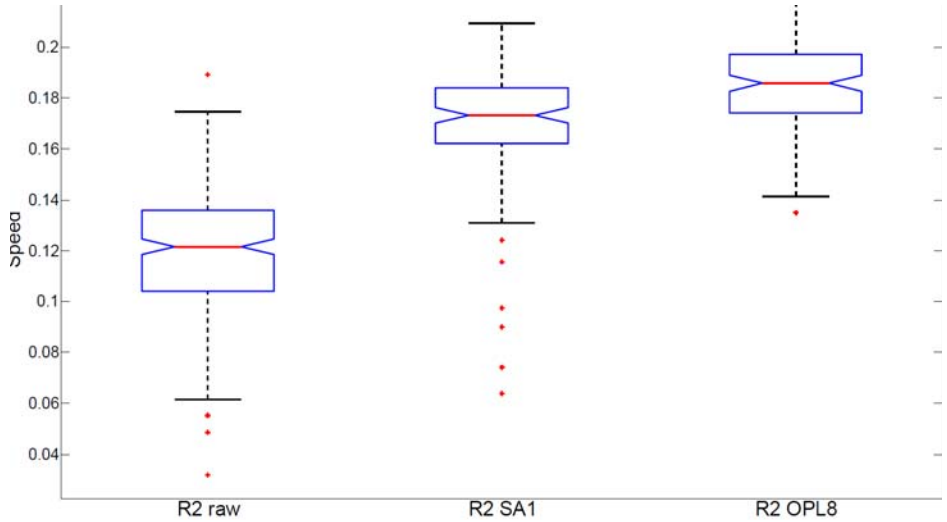
2. Transferability (UPMC, Paris)



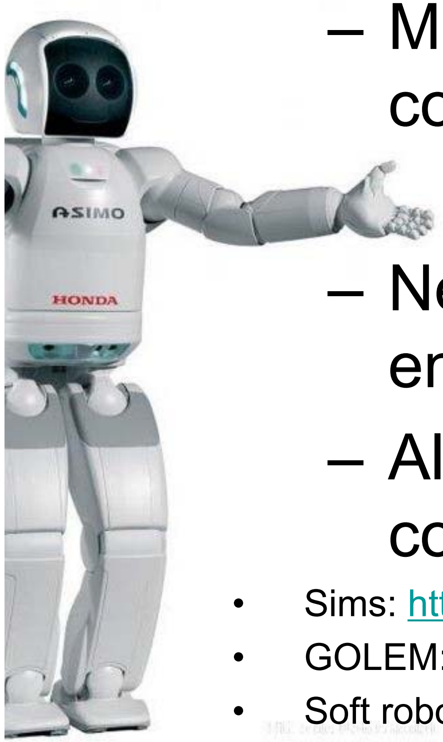
3. Adaptation after transferral (VIDEO)

- Reality gap is «accepted»
- Adaptation algorithm is carried out on the real robot
- Needs to take into account lower number of tests and more noise

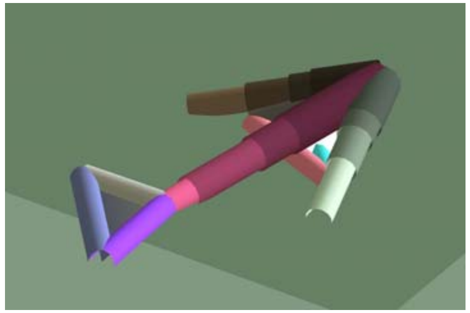


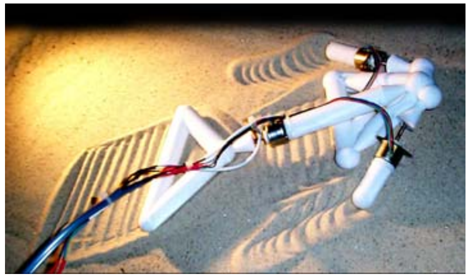


Evolving shape and control



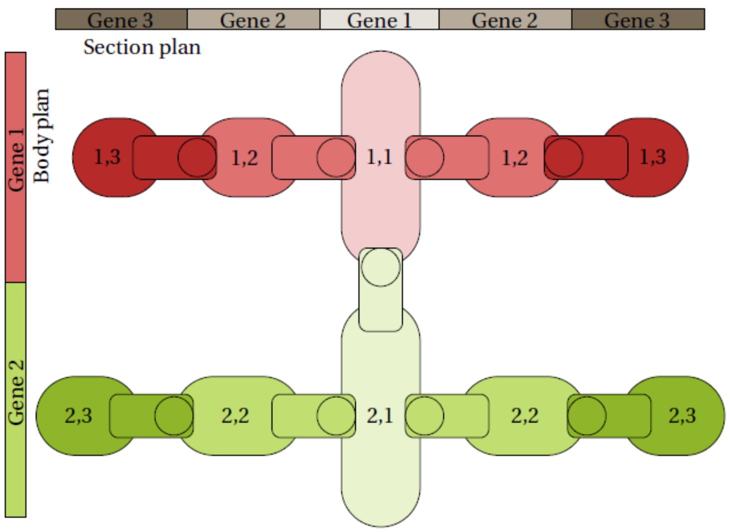
- Physics simulation allows evolution of shape and control simultaneously
  - More efficient designs for complex problems?
  - New designs for new environments?
  - Allows for offloading computation to the body?
- Sims: http://youtu.be/JBgG_VSP7f8
- GOLEM: http://youtu.be/sLtXXFw_q8c
- Soft robot: http://youtu.be/z9ptOeByLA4



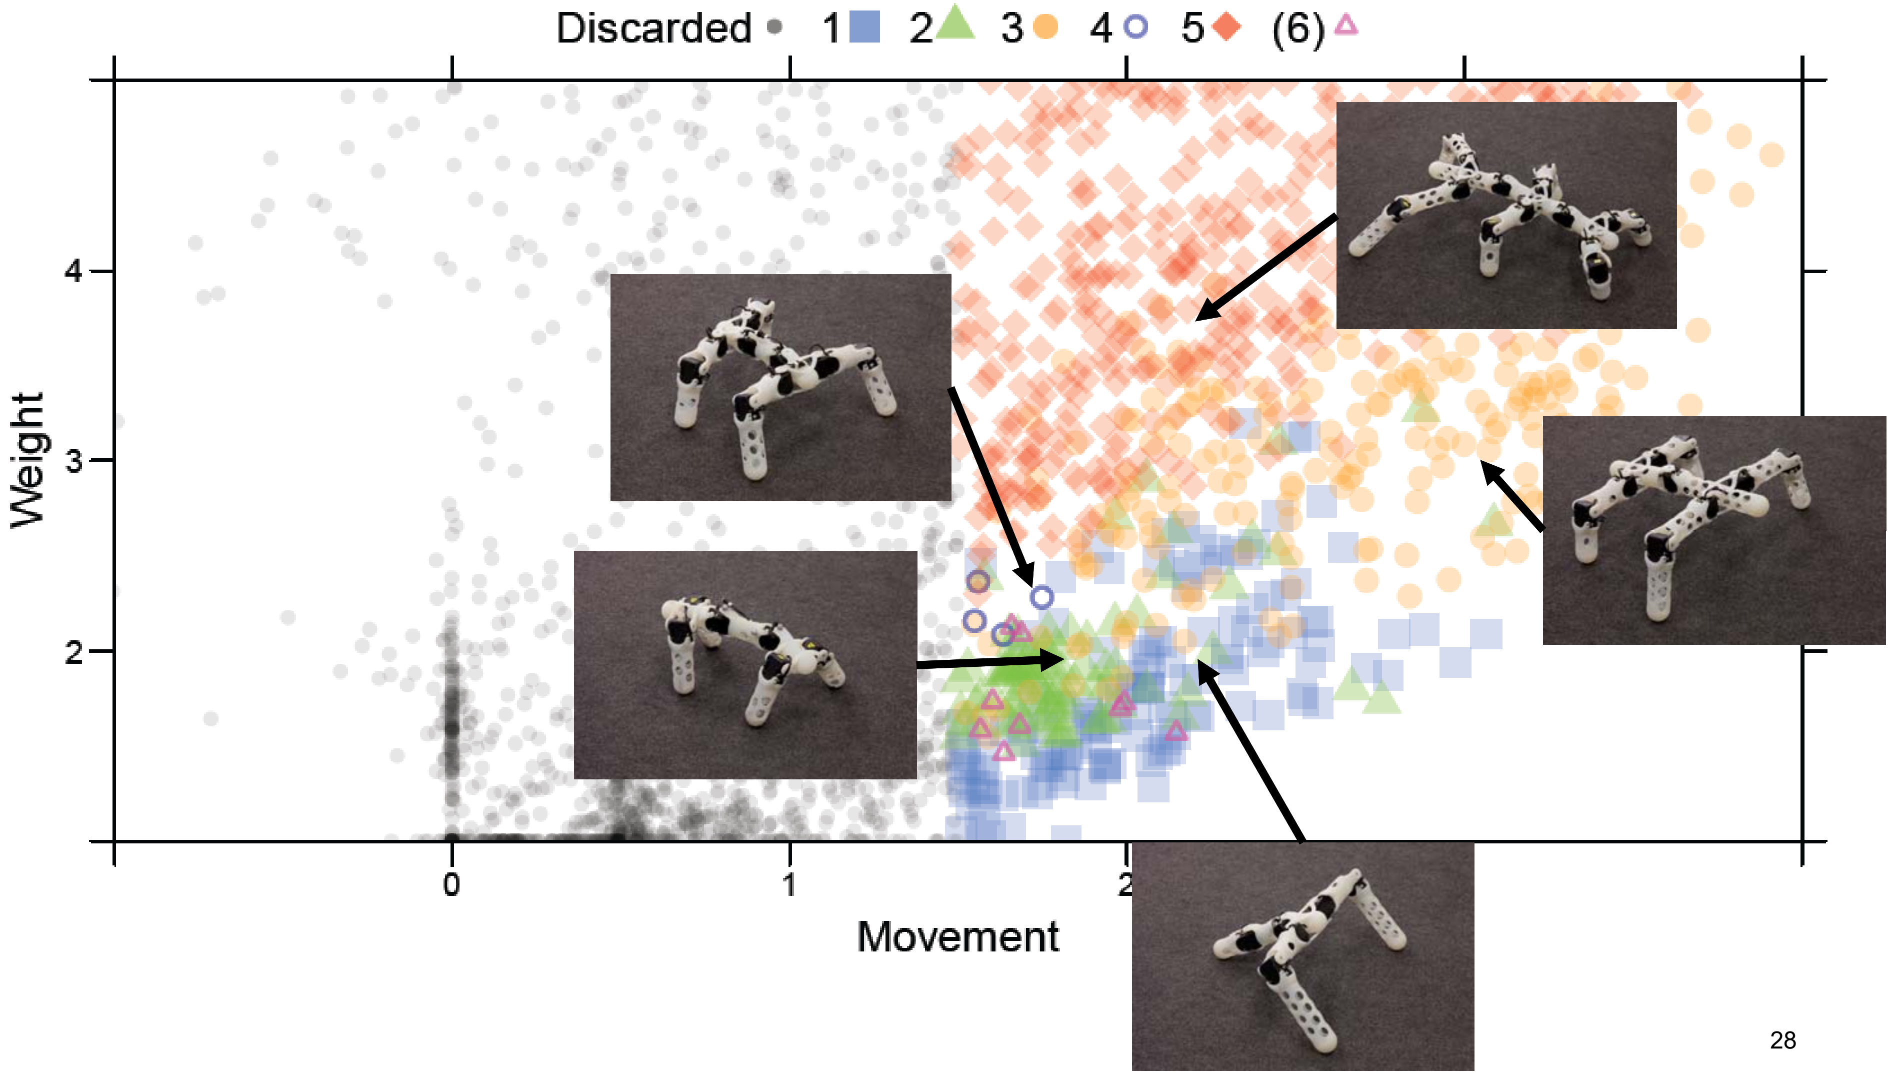


Example: «hox» body evolution

- Generative approach
  - A program builds the robot plan rather than all parameters directly coded
  - Allows a variety of bodies from a compact code
- Designed for production with 3D printer and commercial servos

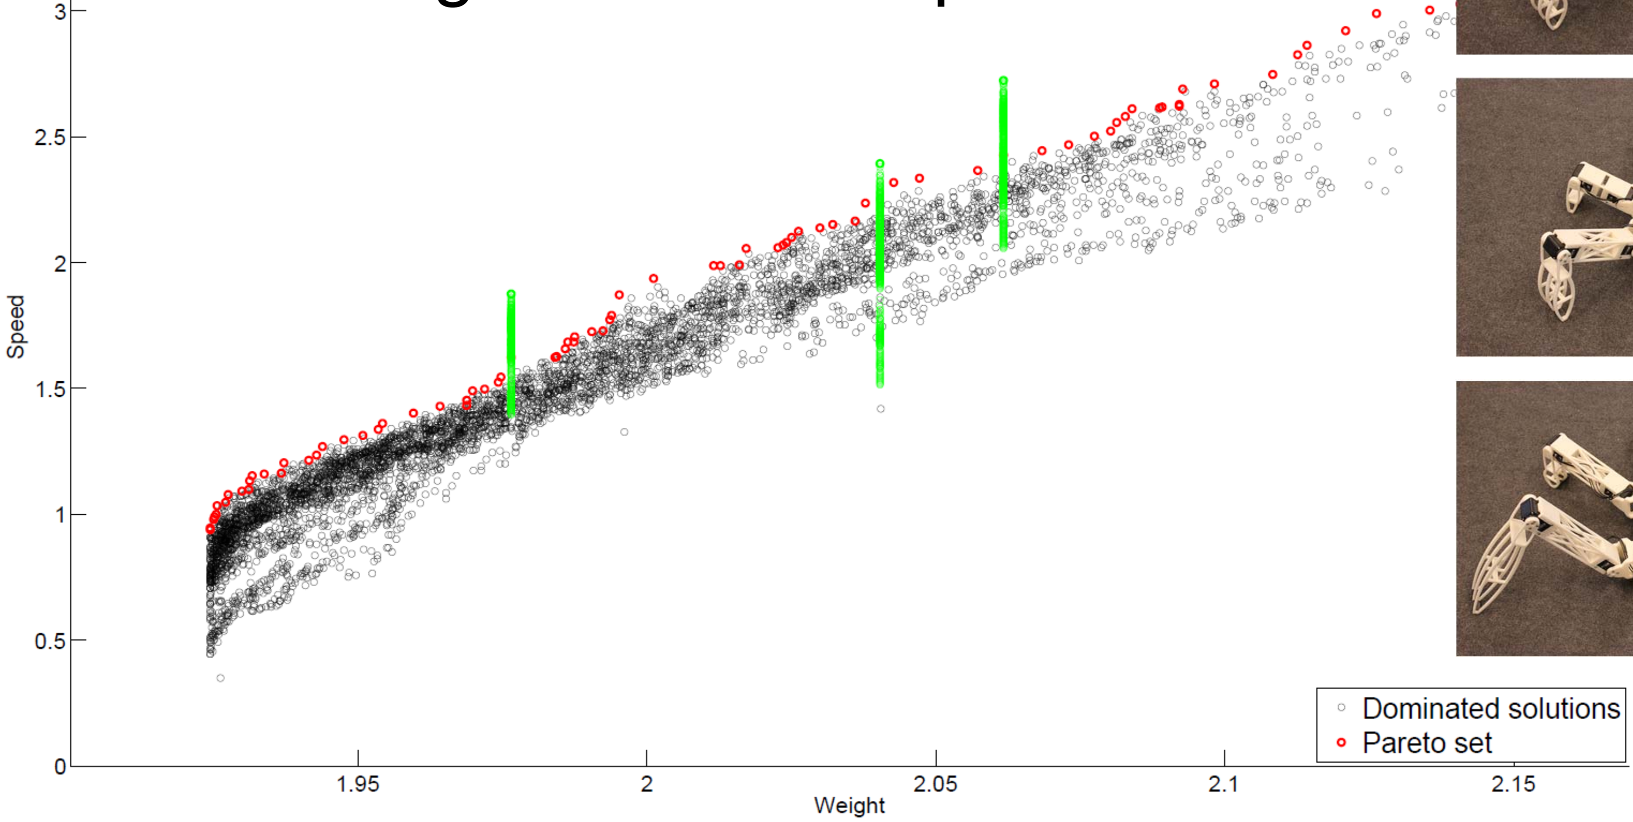


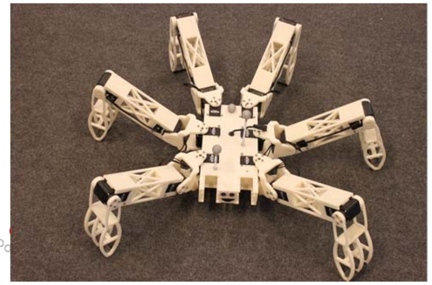
Results: different bodies

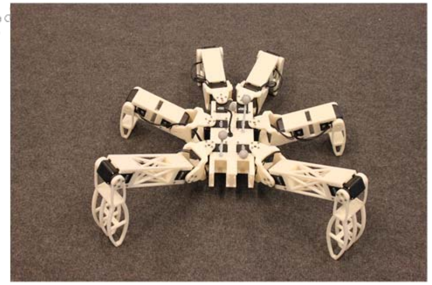


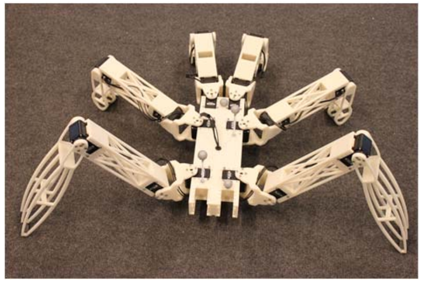
Example MSc project: Karkinos

- Hybrid automatic / engineered design of robot shape and control

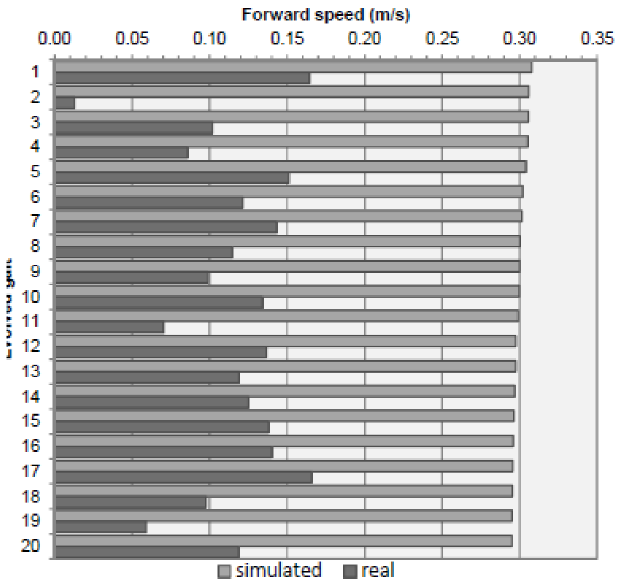




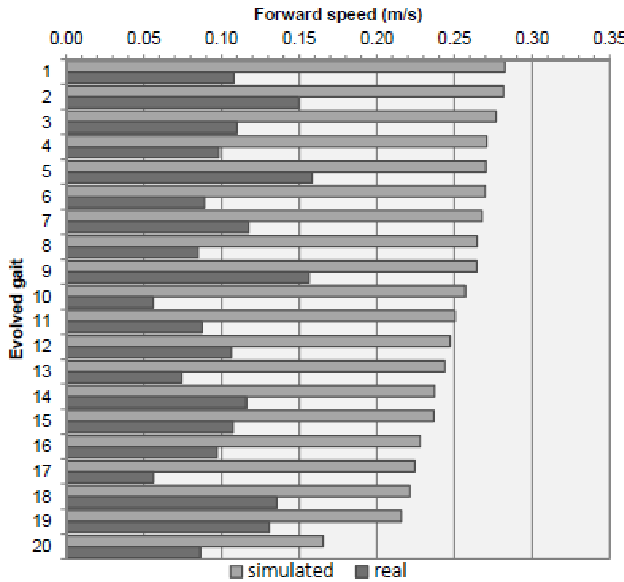




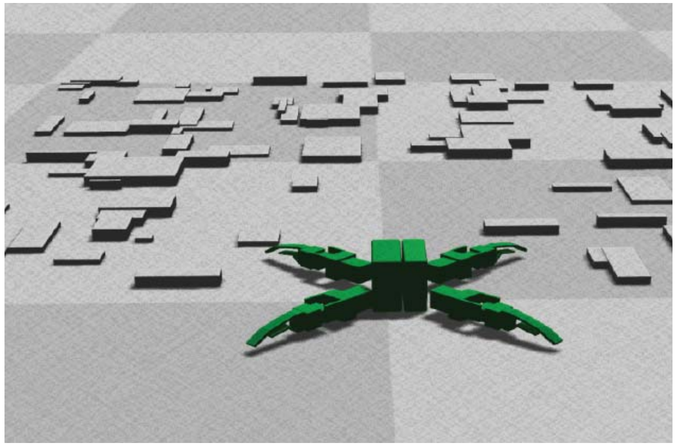
Example MSc project: Reality gap

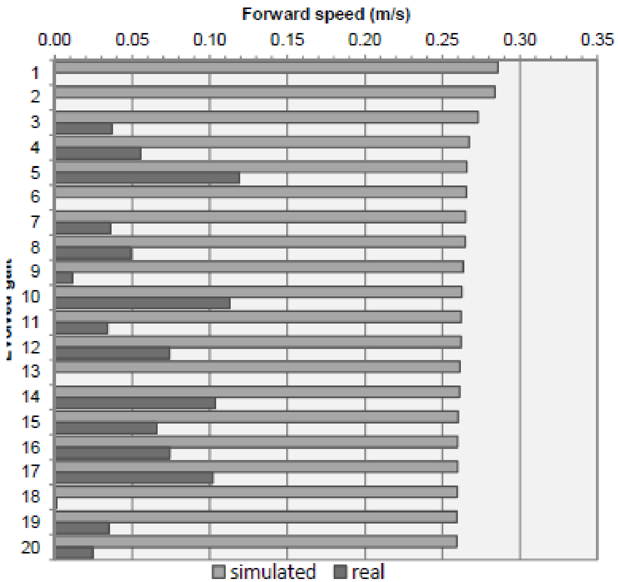


(a) baseline, flat

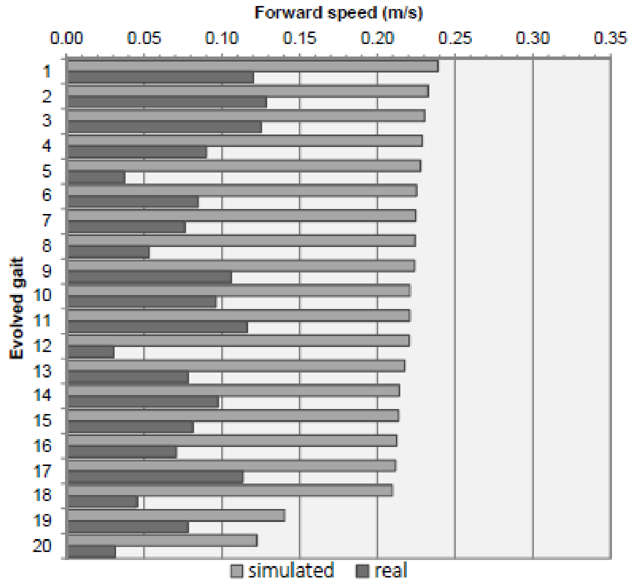


(b) baseline, obstacles

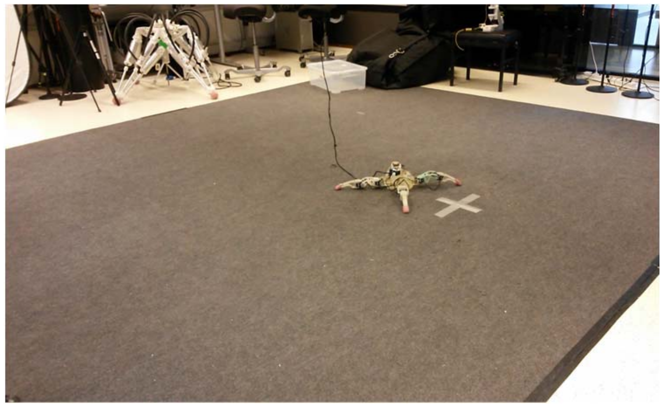




(c) restricted, flat



(d) restricted, obstacles



Summary

- Evolutionary robotics can be useful for adaptation, optimization, design exploration
- Simulation is useful for evolutionary search
- The reality gap remains a research challenge
  - Simulator tuning, transferability, online adaptation
- Co-evolution of body and control gives new possibilities
