

## UiO : Department of Informatics <br> University of Oslo

Biologically inspired computing - Lecture 3

Representations
(Genetic algorithms \& Genetic programming)

## This lecture

- Representations
- Recombination
- Mutation

## Optimization problems

- Continuous optimization
- 0-1 knapsack problem
- Other knapsack problems
- Travelling salesman problem
- Task solving problems

## Real-valued representations

- As shown in the previous lecture
- Represents continuous solution spaces
- The solution parameters are often accompanied by strategy parameters for adaptive normal distribution-based mutation

$$
\begin{array}{|l|l|l|l|l|l|}
\hline 0.1 & 3.3 & 1.7 & 3.4 & 7.2 & 5.9 \\
\hline
\end{array}
$$

## Binary representation

- The representation used in the simple genetic algorithm (SGA)
- Directly inspired by low-level encoding in DNA
- Uses a binary $(0,1)$ coding instead of the quaternary (G,T,A,C) coding used in nature

| 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Integer representation

- Each element is directly coded as an integer
- Usually restricted to some pre-defined ranges

| 0 | 5 | 8 | 3 | 1 | 3 | 7 | 5 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Permutation representation

- Used to solve problems like the travelling salesman
- Known set of actions (go to town X)
- Want to optimize their sequence

## Tree representation

- Tree representations of programs or arithmetic expressions
- Mainly used in genetic programming

## Representations

```
def evol ve():
    P. x = i niti al ize_popul ation()
    P.fitness = eval uate(P.x)
    while not_done():
        Q. x = reproduce(P)
        Q. }x=\mathrm{ mut ate( Q. x)
        Q.fitness = eval uate( Q. x)
        P = survival (P,Q)
        return best(P).x
```

- The central concepts in evolutionary algorithms are independent of representation
- Mutation and recombination must be tailored to the representation used

## Indirect representations

- Most problems will have a fixed solution representation associated with it
- However, sometimes it is beneficial to evolve solutions using a different representation and then transform them to do the evaluation

## Expanding the analogy

| Optimization | Biology |
| :--- | :--- |
| Candidate solution | Individual |
| Representation used in the EA | Genotype, chromosome |
| Problem-defined representation | Phenotype |
| Position/element of the genotype | Locus, gene |
| Old solution | Parent |
| New solution | Offspring |
| Solution quality | Fitness |
| Random displacements added to offspring | Mutation |
| Search strategy | Mutation rate, gene robustness |
| A set of solutions | Population |

University of Oslo

## Binary representation operators

| 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Bit flip mutation

- Each bit is inverted with a probability $p_{m}$

## N-point crossover

- $N$ random points in the genotype is chosen
- At each point the source parent changes

## Uniform crossover

- Which parent to inherit from is chosen randomly for each position
- Identical to discrete recombination

## Binary coding of integers

- Encoding integers as blocks of a binary string has been quite common
- Keeps the analogy to DNA clean
- Problematic because mutations are not local
- Small changes to the solution are not more probable
- The result of flipping a single bit varies enormously with bit position and the value of all bits that encode the same integer

## Integer representation operators

- Can use the same crossover operators as the binary representation

| 0 | 5 | 8 | 3 | 1 | 3 | 7 | 5 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Random reset mutation

- Each element is reset with probability $p_{m}$ to a random number in the range

| 0 | 5 | 8 | 3 | 1 | 3 | 7 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\downarrow$ |  |  |  |  |  |  |  |
| 0 | 7 | 8 | 4 | 1 | 3 | 8 | 1 |

## Creep mutation

- Adds a small value to each element with probability $p_{m}$

| 0 | 5 | 8 | 3 | 1 | 3 | 7 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |
| 0 | 6 | 8 | 2 | 1 | 3 | 8 | 4 |

## Integer coding of symbols

- Sometimes a vector of symbols with no clear order is the most reasonable representation choice
- In such cases, the symbols are usually enumerated and treated as

| Symbol | Value |
| :---: | :---: |
| N | 0 |
| E | 1 |
| S | 2 |
| W | 3 | integers, but without using the creep mutation

## Real-valued representation operators

$$
\begin{array}{|l|l|l|l|l|l|}
\hline 0.1 & 3.3 & 1.7 & 3.4 & 7.2 & 5.9 \\
\hline
\end{array}
$$

## Uniform mutation

- Each element has a probability $p_{m}$ of being replaced with a number from some range

| 0.1 | 3.3 | 1.7 | 3.4 | 7.2 | 5.9 |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :---: | :---: |
| $\downarrow$ |  |  |  |  |  |  |  |
| $\downarrow$ |  |  |  |  |  |  |  |
| 0.1 | 3.3 | 6.1 | 3.4 | 5.0 | 5.9 |  |  |

## Arithmetic recombination

- Makes a copy of one of the parents $x$ and $y$
- Picks one or more random positions $k$ and replaces those elements with the interpolation $\alpha x_{k}+$ $(1-\alpha) y_{k}$, where $\alpha$ is either a fixed number or a random variable.
- Intermediate recombination: $\alpha$ is 0.5 for all $k$

## Single arithmetic recombination

- Arithmetic recombination is applied to only one $k$

## Whole arithmetic recombination

- Arithmetic recombination is applied with the same $\alpha$ to all $k$

## Permutation representation

- Special mutation/recombination operators
- Each item should appear once and only once
- Result should be "close" to the original solution(s)

## Swap Mutation

- Two random elements are swapped
- In some variants neighbors are always chosen

| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |  |
| 1 | 5 | 3 | 4 | 2 | 6 | 7 | 8 |  |

## Insert mutation

- Two random elements are picked
- The second is placed right after the first

| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\checkmark$ |  |  |  |  |  |  |  |
| 1 | 2 | 5 | 3 | 4 | 6 | 7 | 8 |

## Scramble \& invert mutation

- Two random points are selected
- The order of the elements in between is scrambled (scramble mutation) or reversed (invert mutation)

## Partially mapped crossover (PMX)

- Two random points are chosen
- All elements between the points in parent A are copied to the offspring

## Partially mapped crossover (PMX)

- For each element $x$ in parent $B$ between those points that is not in parent $A$
- Place it in the position in B of the element with the same position in $A$ as $x$ has in $B$

## Partially mapped crossover (PMX)

- For each element $x$ in parent $B$ between those points that is not in parent $A$
- Place it in the position in $B$ of the element with the same position in $A$ as $x$ has in $B$
- If that position is occupied, do one more redirection

## Partially mapped crossover (PMX)

- Finally, the missing elements are copied from their places in parent $B$

## Edge crossover

- Heuristic to preserve as many edges as possible

```
def edge_xo(PA, PB, N):
    e = construct_edge_tabl e()
    k = random(N)
    for I in range(1, N):
        X. append(k)
        e. remove(k)
        if e. empty(k): k = reverse(X) [-1]
        if e. empty(k): k = draw( 1, e. remai ni ng())
        el se:
            k = e. pi ck_common(k) or dram(1, e. pi ck_shortest(k))
    return X
```

## Order crossover

- Two random points are chosen
- All elements between the points in parent A are copied to the offspring

## Order crossover

- The rest of the elements are copied from parent B in the order starting from the second random point

## Cycle crossover

- Identify first cycle
- Copy from parent $A$ and $B$ to offspring $A$ and $B$

## Cycle crossover

- Identify next cycle
- Copy from parent $A$ and $B$ to offspring $B$ and $A$

## Cycle crossover

- Identify last cycle
- Copy from parent $A$ and $B$ to offspring $A$ and $B$

University of Oslo

## Tree representation operators

## Tree mutation

- Take a random node and replace it by a new randomly generated subtree

## Tree crossover

- Take one random node from each parent and exchange them

## Bloat in tree representations

- Larger trees will have greater fitness on average in most cases
- Without any active countermeasures the population will tend to grow indefinitely
