Biologically inspired computing – Lecture 4

Selection

Multi-modal and multi-objective problems

Hybrid evolutionary algorithms

Working with evolutionary algorithms

This lecture

- Selection
- Multi-modal problems and diversity
- Multi-objective EAs
- Hybrid EAs
- Working with EAs
 - One-off vs. repetitive use
 - STATISTICS!

Selection

- Parent and survival selection operates independently of the representation
 - Can mix and match with representations
 - Most parent selection algorithms can also be used for survival selection by selecting μ times

Parent selection - fitness proportional selection

- The probability of selecting an individual is proportional to its fitness

$$p_i = \frac{f_i}{\sum_{j=1}^{\mu} f_j}$$

Selection pressure

- Proportional to what?
 - Selection pressure changes by adding different constant offsets to all fitnesses

Fitness near zero

Fitness far from zero

Parent selection – ranking selection

- The probability of selecting an individual is proportional to its rank

$$p_i = \frac{2 - s}{\mu} + \frac{2i(s - 1)}{\mu(\mu - 1)}, \quad s \in (1, 2]$$

Parent selection - tournament selection

- As in evolutionary programming
 - For each parent needed, hold draw k contestants and pick the best one
 - Does not require any global information about the population
 - Gives results similar to ranking selection

Survivor selection – age-based replacement

- Few offspring compared to population size
($\lambda \leq \mu$)
- Number of generations survived \rightarrow age
 - Surviving selected by age

Survivor selection – fitness-based replacement

- As in evolution strategies
 - When $(\lambda \leq \mu)$: replace worst
- Elitism:
 - The very best individuals can survive indefinitely
 - Either a fixed number of elites are kept, or the number is unbounded (e.g. $(\mu + \lambda)$)

Multi-modal problems

Fitness functions usually have multiple local optima, or **modes**

Multi-modal problems

Each of these modes will have a **basin of attraction**, an area around it where a local search would most likely lead to that mode

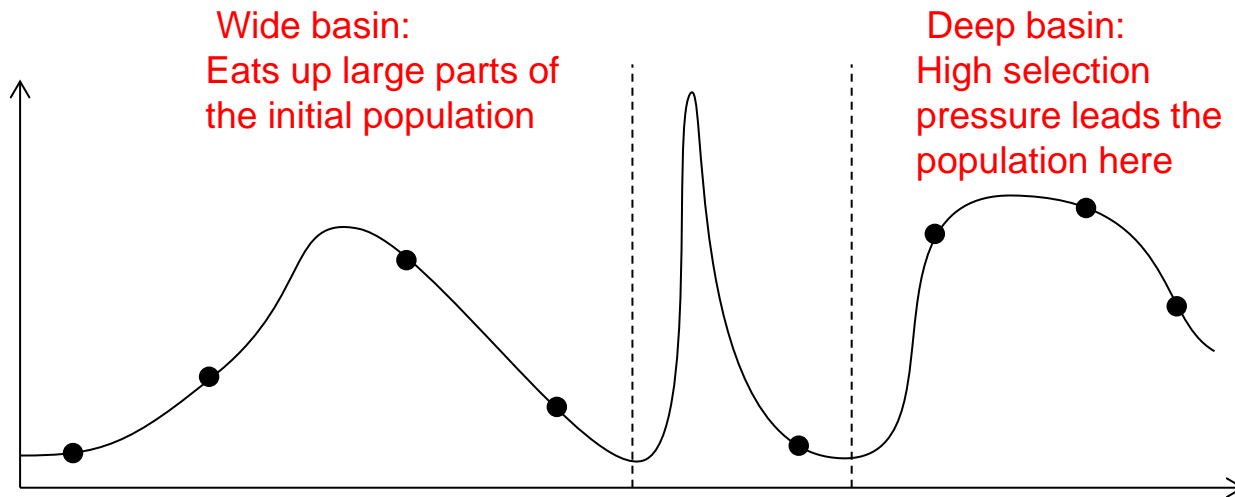

Multi-modal problems

If we're not careful with initialization, we might not get individuals in every basin of attraction

Multi-modal problems

Even when we have initialized really well there are many scenarios that can reduce the survival chances of the “right” individuals

Diversity

- Maintain individuals in as many optima as possible
- Increases the chances of getting and keeping solutions in the basin of the global optima

The island model

- Divide the population into separate “islands”
- Allow only limited migration between islands
(e.g. a couple of individuals every 10th generation)

Diffusion model EAs

- Subpopulations have limited neighborhoods
 - Grids, rings, etc.
- Parent and survivor selection limited to the neighborhood

Fitness sharing

- Decrease the fitness of individuals with neighbors closer than σ_{share}
 - Works best with fitness proportional selection
 - Need distance measure $d_{i,j}$

$$F'_i = \frac{F_i}{\sum_j sh(d_{i,j})} \leq F_i$$

$$sh(d) = \begin{cases} 1 - (d/\sigma_{share})^\alpha & d < \sigma_{share} \\ 0 & \text{else} \end{cases}$$

Crowding

- Two parents create a pair of offspring
- Each offspring competes with their nearest parent for survival
 - Need distance measure

Speciation

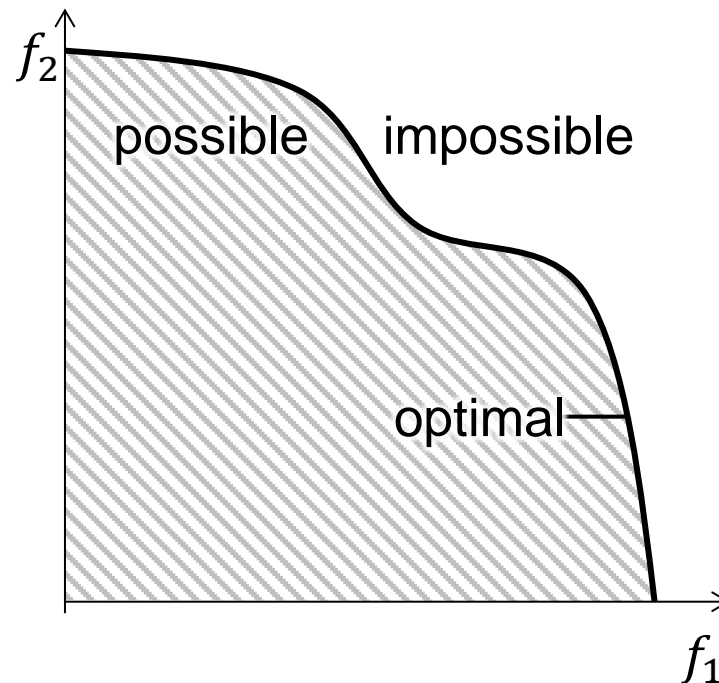

- Define subpopulations dynamically
 - Distance-based clustering
 - Genotype compatibility tags
- Restrict mating to within the subpopulations
- Subpopulation fitness sharing

Multi-objective optimization

- Conflicting considerations
 - Quality
 - Speed
 - Cost
 - etc.

Multi-objective optimization

There is no longer only one optimal solution!

Scalarization

- Use arithmetic to reduce to a single objective
- Objective priorities must be known

$$F = f_1 + af_2 + bf_3$$

$$F = f_1 + f_2 \cdot f_3$$

$$F = e^{f_1} + \tanh f_2 + \mathcal{N}(0, f_3)$$

Weighted sum scalarization

- Most common scalarization
- Weight w_i is chosen based on the importance of objective i

$$F = \sum_{i=1}^M w_i f_i$$

Weighted sum scalarization

The weights define a gradient in objective space

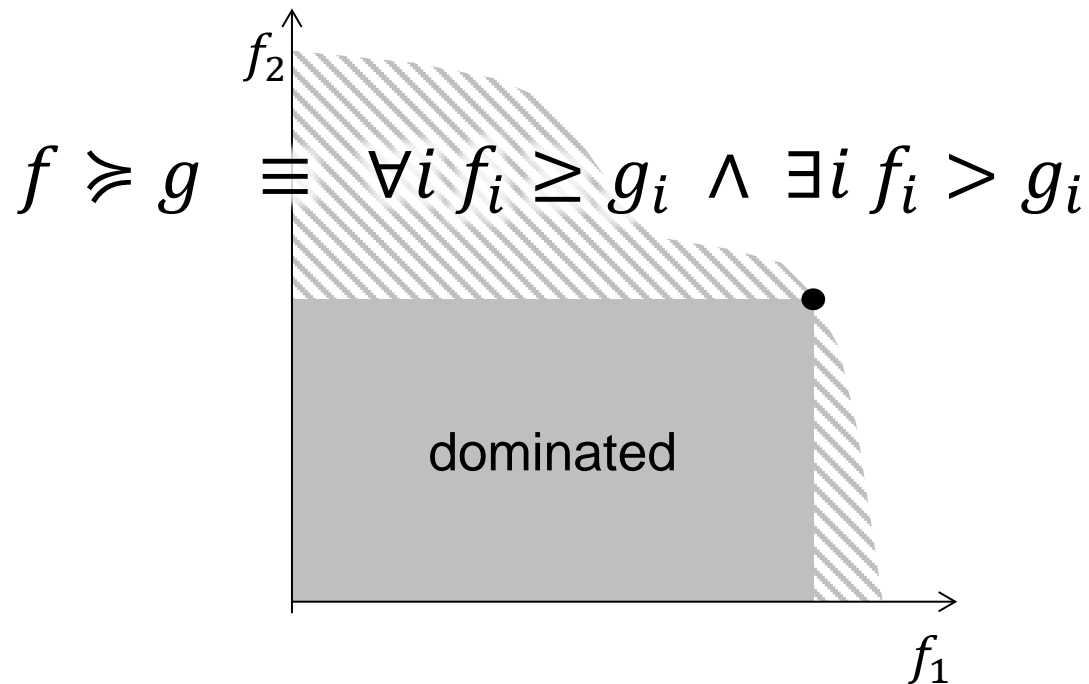

Scalarization

Reducing to a single objective function can create “artificial” local optima

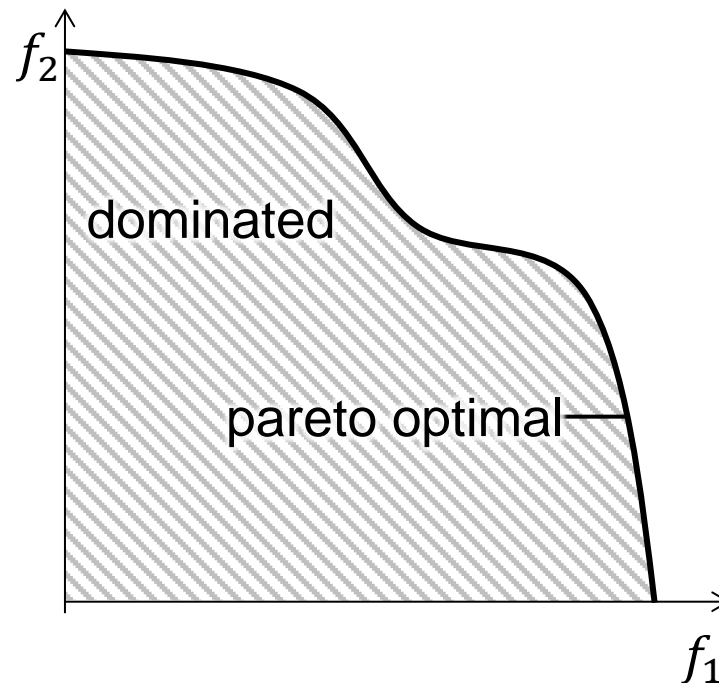

Pareto dominance

A solution dominates another if it is as good in every way and better in at least one

Pareto dominance

Undominated solutions are **Pareto optimal**

Pareto dominance-based EAs

- Only selection operators are affected
- Pareto dominance replaces scalar comparison
 - Usually a secondary diversity measure is used for mutually non-dominated solutions:

```
def better_mo(a, b):  
    if dominates(a, b): return true  
    if dominates(b, a): return false  
    return diversity(a) > diversity(b)
```
 - Tournament selection
 - Selection proportional to the number of solutions that are dominated in the population

Non-dominated sorting

```
def nondominated_sort(P):  
    Q = P  
    P = []  
    rank = 1  
    while not Q.empty():  
        F = Q.nondominated()  
        Q.remove(F)  
        F.assign_rank(rank)  
        P.insert(F)  
        rank = rank+1  
    return P
```

Sorts the population into layers by domination

Elitism and MOEAs

- Most modern multi-objective evolutionary algorithms use some form of elitism
 - $(\mu + \lambda)$
 - Separate population (archive)

Hybrid EAs

- In many cases, decent heuristics or local search algorithms exist
- These algorithms can often be integrated into an evolutionary algorithm either to speed up the process or improve solution quality

Hybrid EAs

| Optimization | Biology |
|--|--------------------------------|
| Candidate solution | Individual |
| Representation used in the EA | Genotype, chromosome |
| Problem-defined representation | Phenotype |
| Position/element of the genotype | Locus, gene |
| Local search algorithm during evaluation | Learning |
| Old solution | Parent |
| New solution | Offspring |
| Solution quality | Fitness |
| Random displacements added to offspring | Mutation |
| Search strategy | Mutation rate, gene robustness |
| A set of solutions | Population |

Memetic algorithms

- Meme: An evolving cultural entity
- Another term for hybrid EAs

Memetic algorithms

- Can be added at many stages
 - Clever initialization
 - Local search during evaluation
 - Problem-specific heuristics in mutation, crossover and selection

In initialization

- Seeding
 - Known good solutions are added
- Selective initialization
 - Generate kN solutions, keep best N
- Refined start
 - Perform local search on initial population

Intelligent mutation and crossover

- Mutation bias
 - Mutation operator has bias towards certain changes
- Crossover hill-climber
 - Test all 1-point crossover results, choose best
- “Repair” mutation
 - Use heuristic to make infeasible solution feasible

Learning and evolution

- Do offspring inherit what their parents have learnt in life?
 - Yes - Lamarckian learning
 - Improved fitness and genotype
 - No - Baldwinian learning:
 - Improved fitness only

Working with evolutionary algorithms

What do you want your EA to do?

Design problems

- Only need to be done once
- End result must be excellent

Design problem example

- Optimizing spending on improvements to national road network
 - Total cost: billions of Euro
 - Computing costs negligible
 - Six months on hundreds of computers
 - Many runs possible
 - Must produce *very* good result just *once*

Repetitive problems

- Has to be run repeatedly
- Should produce OK results quickly and reliably

Repetitive problem example

- Optimizing postal delivery routes
 - Different destinations each day
 - Limited time to run algorithm each day
 - Must *always* perform *reasonably* well in limited time

Research and development

- Must produce repeatable, unbiased results
- Engineering decisions
- Academic publishing

R&D topics

- Show that an EA is applicable in some problem domain
- Show that (your fancy new) EA outperforms benchmark EA/some traditional algorithm
- Optimize or study impact of some parameters for an EA
- Investigate algorithm behavior or performance

STATISTICS

- Evolutionary algorithms are stochastic
 - Result will vary from run to run
 - Many runs are needed to say anything concrete about the performance of the EA
 - Use statistics and statistical measures!
- Do proper science!
 - Same measures
 - Fair comparisons

Things to measure

- Average result in given time
- Average time for given result
- Best result over N runs
- Proportion of X or amount of Y required to do Z under conditions W
- Etc.

Off-line performance measures

- Efficiency (speed)
 - Time
 - Average number of evaluations to solution (AES)
- Effectiveness (quality)
 - Success rate (SR)
 - Mean best fitness at termination (MBF)
 - Mean across runs, best of each run

On-line performance measures

- Population distribution (genotypic)
- Fitness distribution (phenotypic)
- Improvements per time unit or per genetic operator

What time units do we use?

- Elapsed time?
 - Depends on computer, network, etc.
- CPU time?
 - Depends on skill of programmer, implementation, etc.
- Generations?
 - Incomparable when parameters like population size change
- Evaluations?
 - Evaluation time could be small compared to “overhead”:
 - (Hybrid) selection, mutation and crossover
 - Genotype-phenotype translation

STATISTICS!

| Trial | Old method | New Method |
|---------|------------|------------|
| 1 | 500 | 657 |
| 2 | 600 | 543 |
| 3 | 556 | 654 |
| 4 | 573 | 565 |
| 5 | 420 | 654 |
| 6 | 590 | 712 |
| 7 | 700 | 456 |
| 8 | 472 | 564 |
| 9 | 534 | 675 |
| 10 | 512 | 643 |
| Average | 545.7 | 612.3 |

STATISTICS!

| Trial | Old method | New Method |
|----------|---|------------|
| 1 | 500 | 657 |
| 2 | 600 | 543 |
| 3 | 556 | 654 |
| 4 | 573 | 565 |
| 5 | 420 | 654 |
| 6 | 590 | 712 |
| 7 | 700 | 456 |
| 8 | 472 | 564 |
| 9 | 534 | 675 |
| 10 | 512 | 643 |
| Average | 545.7 | 612.3 |
| σ | 73.60 | 73.55 |
| T-test | 0.0708 <u>NO STATISTICAL SIGNIFICANCE</u> | |

STATISTICS!

- Don't trust the averages
 - Extra important when the sample is small
- Always check the deviation
 - For normal distributions, use standard deviation
 - Interquartile range (1st quartile – 3rd quartile) is also good
 - Range (max – min) is better than nothing

STATISTICS!

- T-tests, use them
 - Alternatively, the simpler Z-test is approximately equivalent for good sample sizes ($N \geq 100$)
 - Different tests also exist
 - Wilcoxon
 - F-test
 - Wikipedia might be able to point out the right test
