

INF3490 - Biologically inspired computing

Lecture 2: Eiben and Smith, chapter 1-4

Evolutionary Algorithms -Introduction and representation

Jim Tørresen

:H

Evolution

• Biological evolution:

- Lifeforms adapt to a particular environment over successive generations.
- Combinations of traits that are better adapted tend to increase representation in population.
- Mechanisms: Selection+Crossover, Mutation and Survival of the fittest.

• Evolutionary Computing (EC):

- Mimic the biological evolution to optimize solutions to a wide variety of complex problems.
- In every new generation, a new set of solutions is created using bits and pieces of the fittest of the old.

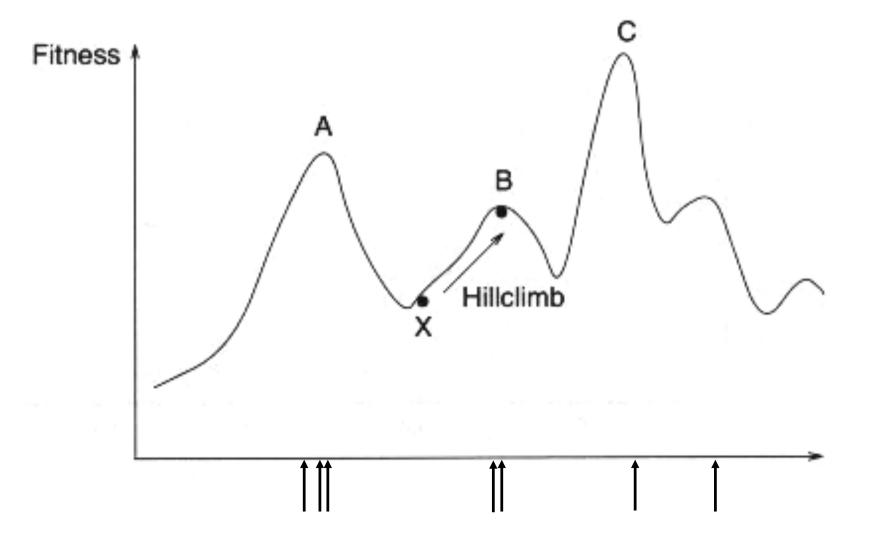

Evolution in Nature

- A population of individuals exists in an environment with limited resources
- **Competition** for those resources causes selection of those *fitter* individuals that are better adapted to the environment
- These individuals act as seeds for the generation of new individuals through recombination and mutation
- The new individuals have their fitness evaluated and compete (possibly also with parents) for survival.
- Over time *Natural selection* causes a rise in the fitness of the population

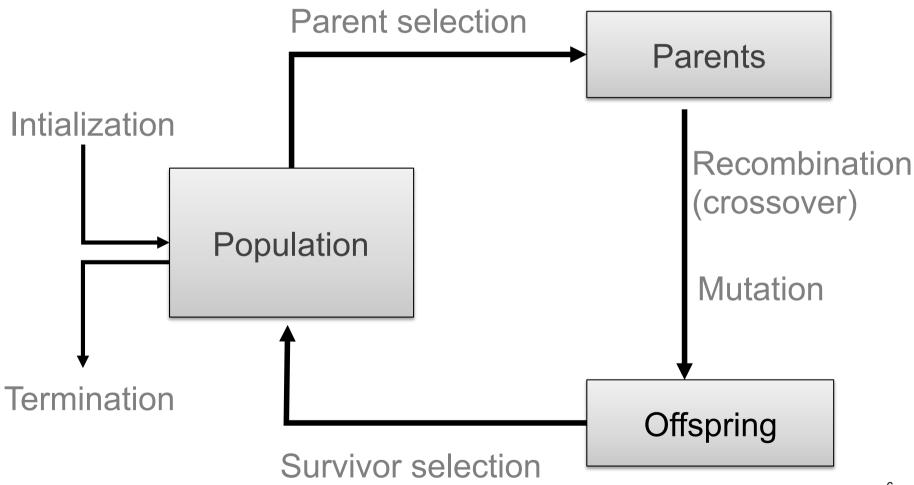

Evolutionary Algorithms (EAs)

- EAs fall into the category of "generate and test" algorithms
- They are stochastic, population-based algorithms
- Variation operators (recombination and mutation) create the necessary diversity and thereby facilitate novelty
- Selection reduces diversity and acts as a force pushing quality

Hillclimbing Problem in Search

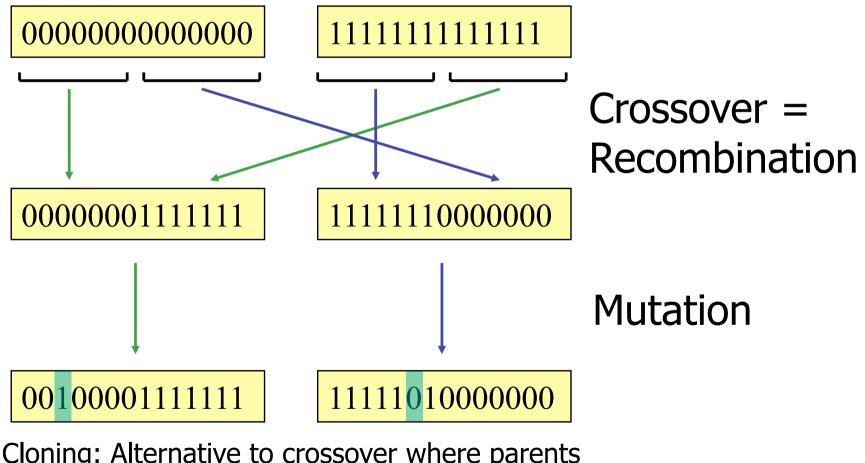

General scheme of EAs

EA scheme in pseudo-code

```
BEGIN
    INITIALISE population with random candidate solutions;
    EVALUATE each candidate;
    REPEAT UNTIL ( TERMINATION CONDITION is satisfied ) DO
    1 SELECT parents;
    2 RECOMBINE pairs of parents;
    3 MUTATE the resulting offspring;
    4 EVALUATE new candidates;
    5 SELECT individuals for the next generation;
    OD
END
```

Evolutionary Operators

Cloning: Alternative to crossover where parents are copied to the offspring

Scheme of an EA: Common model of evolutionary processes

- Population of individuals
- Individuals have a fitness
- Variation operators: crossover, mutation
- Selection towards higher fitness
 - "survival of the fittest" and
 - "mating of the fittest"

Optimization according to some fitness-criterion (optimization on a fitness landscape)

Scheme of an EA: Two pillars of evolution

There are two competing forces

Increasing population **diversity** by genetic operators

- mutation
- recombination

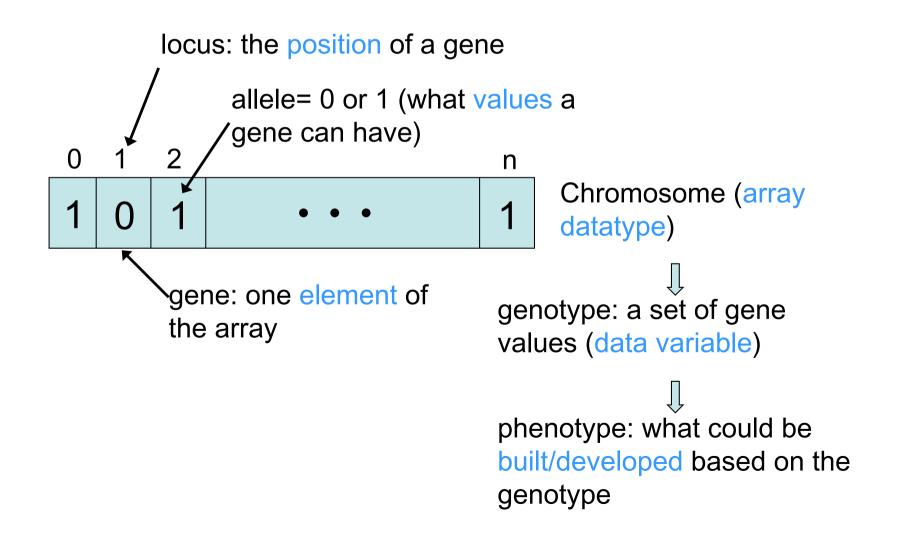

Push towards **novelty**

Decreasing population **diversity** by selection

- of parents
- of survivors

Push towards quality

Representation: EA terms

Main EA components: Evaluation (fitness) function

- Role:
 - Represents the task to solve, the requirements to adapt to (can be seen as "the environment")
 - Enables selection (provides basis for comparison)
 - e.g., some phenotypic traits are advantageous, desirable,
 e.g. big ears cool better, these traits are rewarded by more offspring that will expectedly carry the same trait
- A.k.a. *quality* function or *objective* function
- Assigns a single real-valued fitness to each phenotype which forms the basis for selection
- Typically we talk about fitness being maximised
 - Some problems may be best posed as minimisation problems, but conversion is trivial

Main EA components: Population

- Role: holds the candidate solutions of the problem as individuals (genotypes)
- Formally, a population is a multiset of individuals, i.e. repetitions are possible
- Population is the basic unit of evolution, i.e., the population is evolving, not the individuals
- Selection operators act on population level
- Variation operators act on individual level

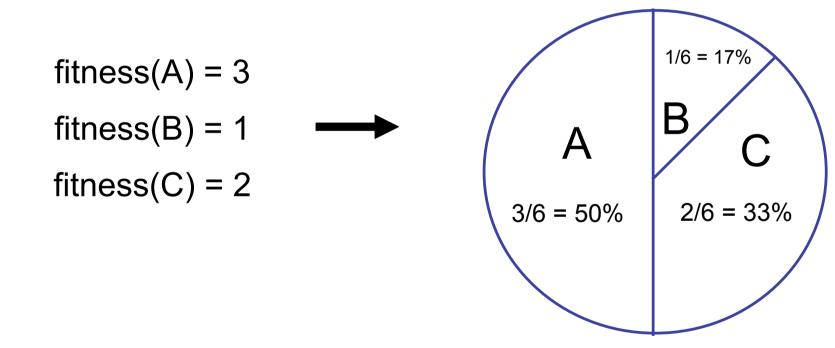

Main EA components: Selection mechanism (1/3)

Role:

- Identifies individuals
 - to become parents
 - to survive
- Pushes population towards higher fitness
- Usually probabilistic
 - high quality solutions more likely to be selected than low quality
 - but not guaranteed
 - even worst in current population usually has non-zero probability of being selected
- This stochastic nature can aid escape from local optima 14

Main EA components: Selection mechanism (2/3)

Example: roulette wheel selection

In principle, any selection mechanism can be used for **parent selection** as well as for **survivor selection**

Main EA components: Selection mechanism (3/3)

- Survivor selection a.k.a. replacement
- Most EAs use fixed population size so need a way of going from (parents + offspring) to next generation
- Often deterministic (while parent selection is usually stochastic)
 - Fitness based: e.g., rank parents + offspring and take best
 - Age based: make as many offspring as parents and delete all parents
- Sometimes a combination of stochastic and deterministic (elitism)

Main EA components: What are the different types of EAs

- Historically different flavours of EAs have been associated with different data types to represent solutions
 - Binary strings : Genetic Algorithms (GA)
 - Real-valued vectors : Evolution Strategies (ES)
 - Finite state Machines: Evolutionary Programming (EP)
 - LISP trees: Genetic Programming (GP)
- These differences are largely irrelevant, best strategy
 - choose representation to suit problem
 - choose variation operators to suit representation
- Selection operators only use fitness and so are independent of representation

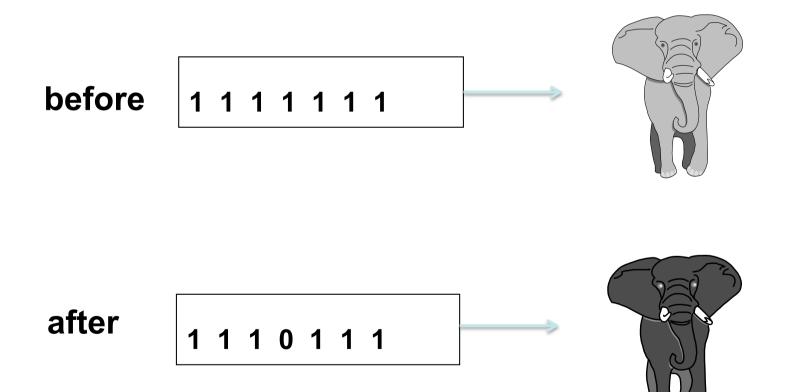

Main EA components: Variation operators

- Role: to generate new candidate solutions
- Usually divided into two types according to their **arity** (number of inputs to the variation operator):
 - Arity 1 : **mutation** operators
 - Arity >1 : recombination operators
 - Arity = 2 typically called crossover
 - Arity > 2 is formally possible, seldom used in EC
- There has been much debate about relative importance of recombination and mutation
 - Nowadays most EAs use both
 - Variation operators must match the given representation

Main EA components: Mutation (1/2)

- Role: causes small, random variance
- Acts on one genotype and delivers another
- Element of randomness is essential and differentiates it from other unary heuristic operators
- Importance ascribed depends on representation and historical dialect:
 - Binary GAs background operator responsible for preserving and introducing diversity
 - EP for FSM's / continuous variables the only search operator
 - GP hardly used
- May guarantee connectedness of search space and hence convergence proofs

Main EA components: Mutation (2/2)

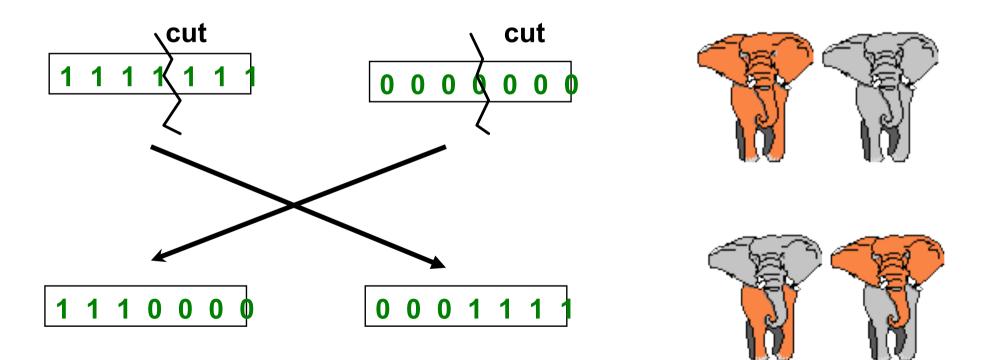

Main EA components: Recombination (1/2)

- Role: merges information from parents into offspring
- Choice of what information to merge is stochastic
- Most offspring may be worse, or the same as the parents
- Hope is that some are better by combining elements of genotypes that lead to good traits
- Principle has been used for millennia by breeders of plants and livestock

Main EA components: Recombination (2/2)

Parents

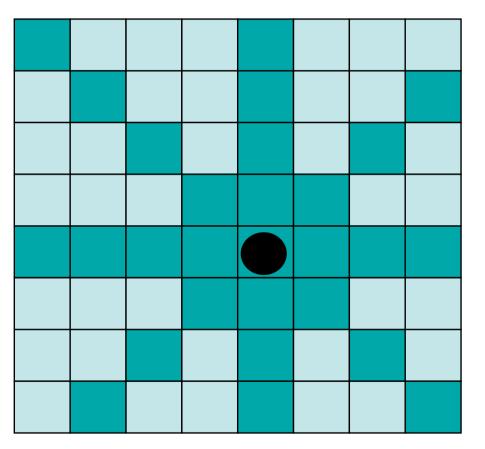

Offspring

Main EA components: Initialisation / Termination

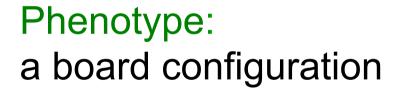

- Initialisation usually done at random,
 - Need to ensure even spread and mixture of possible allele values
 - Can include existing solutions, or use problem-specific heuristics, to "seed" the population
- Termination condition checked every generation
 - Reaching some (known/hoped for) fitness
 - Reaching some maximum allowed number of generations
 - Reaching some minimum level of diversity
 - Reaching some specified number of generations without fitness improvement

Example: The 8-queens problem

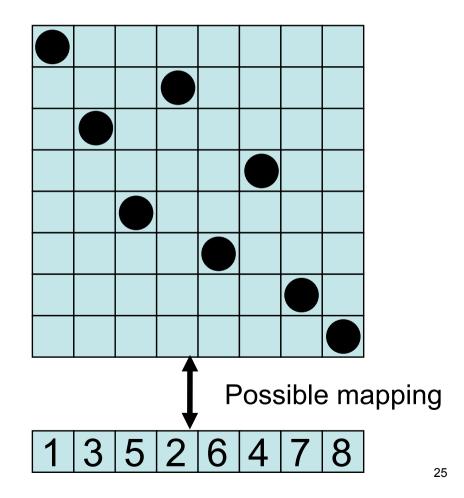

Place 8 queens on an 8x8 chessboard in such a way that they cannot check each other ²⁴

The 8-queens problem: Representation

Genotype: a permutation of the numbers 1–8

The 8-queens problem: Fitness evaluation

- Penalty of one queen: the number of queens she can check
- Penalty of a configuration: the sum of penalties of all queens
- Note: penalty is to be minimized
- Fitness of a configuration: inverse penalty to be maximized

The 8-queens problem: Mutation

Small variation in one permutation, e.g.:

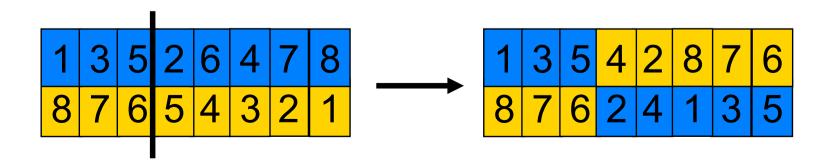

• swapping values of two randomly chosen positions,

The 8-queens problem: Recombination

Combining two permutations into two new permutations:

- choose random crossover point
- copy first parts into children
- create second part by inserting values from other parent:
 - in the order they appear there
 - beginning after crossover point
 - skipping values already in child

The 8-queens problem: Selection

- Parent selection:
 - Pick 5 parents and take best two to undergo crossover
- Survivor selection (replacement)
 - When inserting a new child into the population, choose an existing member to replace by:
 - sorting the whole population by decreasing fitness
 - enumerating this list from high to low
 - replacing the first with a fitness lower than the given child

Typical EA behaviour: Stages

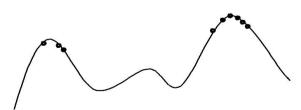

Stages in optimising on a 1-dimensional fitness landscape

Early stage: quasi-random population distribution

Mid-stage: population arranged around/on hills

Late stage:

population concentrated on high hills

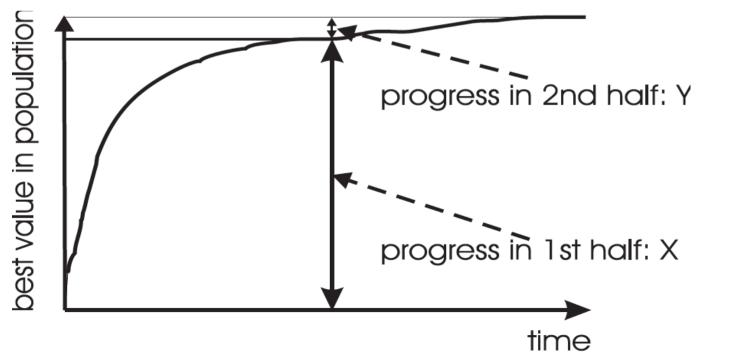

Typical EA behaviour: Typical run: progression of fitness

Typical run of an EA shows so-called "anytime behavior"

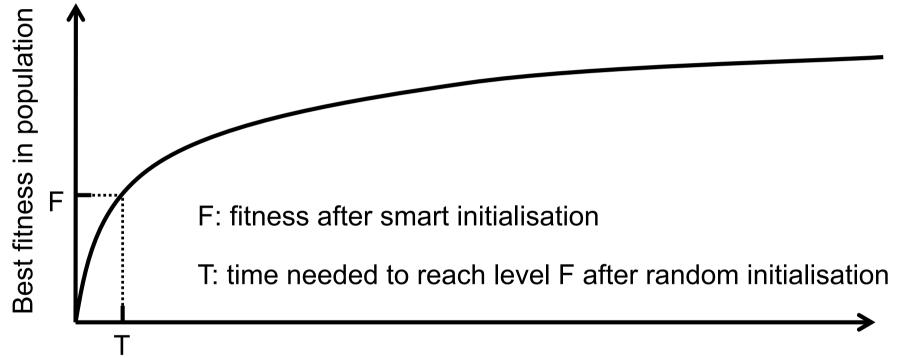

Typical EA behaviour: Are long runs beneficial?

- Answer:
 - It depends on how much you want the last bit of progress
 - May be better to do more short runs

32

Typical EA behaviour: Is it worth expending effort on smart initialisation?

Time (number of generations)

- Answer: it depends.
 - Possibly good, if good solutions/methods exist.
 - Care is needed, see chapter/lecture on hybridisation.

Typical EA behaviour: Evolutionary Algorithms in context

- There are many views on the use of EAs as robust problem solving tools
- For most problems a problem-specific tool may:
 - perform better than a generic search algorithm on most instances,
 - have limited utility => not do well on all instances
- Goal is to provide robust tools that provide:
 - evenly good performance over a range of problems and instances

Typical EA behaviour: EAs and domain knowledge

- Trend in the 90's: adding problem specific knowledge to EAs (special variation operators, repair, etc)
- Result: EA performance curve "deformation":
 - better on problems of the given type
 - worse on problems different from given type
 - amount of added knowledge is variable
- Recent theory suggests the search for an "allpurpose" algorithm may be fruitless

Chapter 4: Representation, Mutation, and Recombination

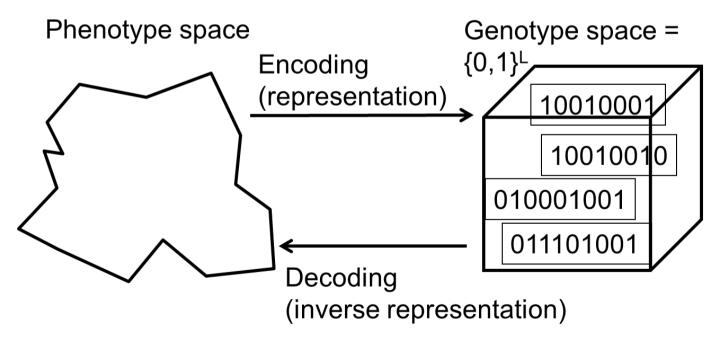

- Role of representation and variation operators
- Most common representation of genomes:
 - Binary
 - Integer
 - Real-Valued or Floating-Point
 - Permutation
 - Tree

Role of representation and variation operators

- First stage of building an EA and most difficult one: choose *right* representation for the problem
- Variation operators: mutation and crossover
- Type of variation operators needed depends on chosen representation
- TSP problem
 - What are possible representations?

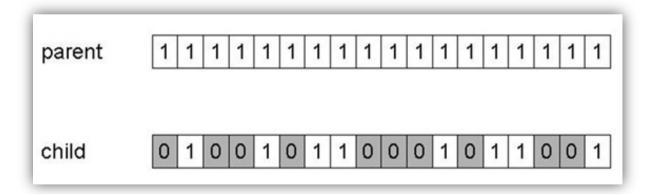

Binary Representation

- One of the earliest representations
- Genotype consists of a string of binary digits

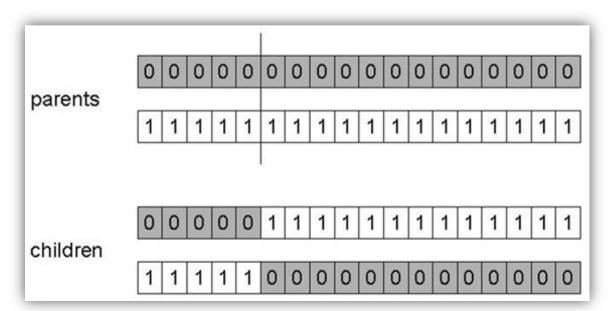

Binary Representation: Mutation

- Alter each gene independently with a probability p_m
- p_m is called the mutation rate
 - Typically between 1/pop_size and 1/ chromosome_length

Binary Representation: 1-point crossover

- Choose a random point on the two parents
- Split parents at this crossover point
- Create children by exchanging tails
- P_c typically in range (0.6, 0.9)

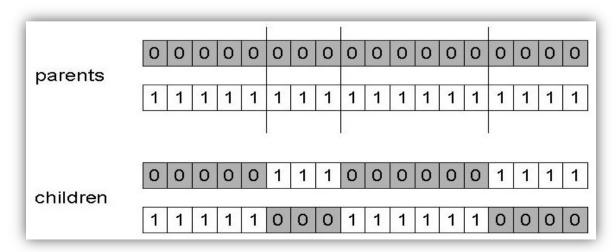

Binary Representation: Alternative Crossover Operators

- Why do we need other crossover(s)?
- Performance with 1-point crossover depends on the order that variables occur in the representation
 - More likely to keep together genes that are near each other
 - Can never keep together genes from opposite ends of string
 - This is known as Positional Bias
 - Can be exploited if we know about the structure of our problem, but this is not usually the case

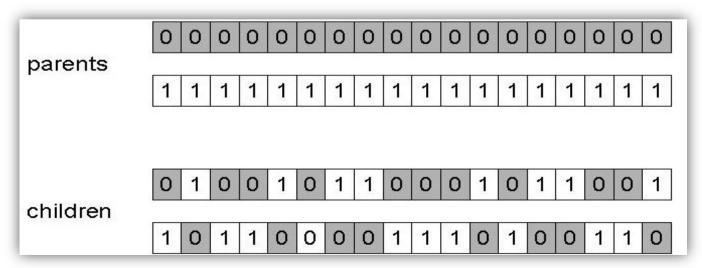

Binary Representation: n-point crossover

- Choose n random crossover points
- Split along those points
- Glue parts, alternating between parents
- Generalisation of 1-point (still some positional bias)

Binary Representation: Uniform crossover

- Assign 'heads' to one parent, 'tails' to the other
- Flip a coin for each gene of the first child
- Make an inverse copy of the gene for the second child
- Inheritance is independent of position

Binary Representation: Crossover OR mutation? (1/3)

Decade long debate:

- which one is better / necessary ?

- Answer (at least, rather wide agreement):
 - it depends on the problem, but
 - in general, it is good to have both
 - both have a different role
 - mutation-only-EA is possible, x-over-only-EA would not work

Binary Representation: Crossover OR mutation? (2/3)

Exploration: Discovering promising areas in the search space, i.e. gaining information on the problem

Exploitation: Optimising within a promising area, i.e. using information

There is co-operation AND competition between them:

• **Crossover** is **explorative**, it makes a *big* jump to an area somewhere "in between" two (parent) areas

• **Mutation** is **exploitative**, it creates random *small* diversions, thereby staying near (in the area of) the parent 45

Binary Representation: Crossover OR mutation? (3/3)

- Only crossover can combine information from two parents
- Only mutation can introduce new information (alleles)
- To hit the optimum you often need a 'lucky' mutation

Integer Representation

- Nowadays it is generally accepted that it is better to encode numerical variables directly (integers, floating point variables)
- Some problems naturally have integer variables, e.g. image processing parameters
- Others take categorical values from a fixed set e.g. {blue, green, yellow, pink}
- N-point / uniform crossover operators work
- Extend bit-flipping mutation to make
 - "creep" i.e. more likely to move to similar value
 - Adding a small (positive or negative) value to each gene with probability p
 - Random resetting (esp. categorical variables)
 - With probability p_m a new value is chosen at random
- Same recombination as for binary representation

Real-Valued or Floating-Point Representation: Uniform Mutation

- General scheme of floating point mutations $\overline{x} = \langle x_1, ..., x_l \rangle \rightarrow \overline{x}' = \langle x'_1, ..., x'_l \rangle$ $x_i, x'_i \in [LB_i, UB_i]$
- Uniform Mutation

 x'_i drawn randomly (uniform) from $[LB_i, UB_i]$

Analogous to bit-flipping (binary) or random resetting (integers)

Real-Valued or Floating-Point Representation: Nonuniform Mutation

- Non-uniform mutations:
 - Many methods proposed, such as time-varying range of change etc.
 - Most schemes are probabilistic but usually only make a small change to value
 - Most common method is to add random deviate to each variable separately, taken from N(0, σ)
 Gaussian distribution and then curtail to range

 $x'_{i} = x_{i} + N(0,\sigma)$

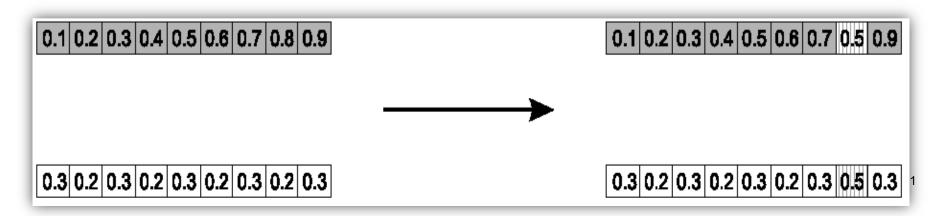

- Standard deviation σ , *mutation step size*, controls amount of change (2/3 of drawings will lie in range (- σ to + σ))

Real-Valued or Floating-Point Representation: Crossover operators

- Discrete:
 - each allele value in offspring z comes from one of its parents (x,y) with equal probability: $z_i = x_i$ or y_i
 - Could use n-point or uniform
- Intermediate
 - exploits idea of creating children "between" parents (hence a.k.a. *arithmetic* recombination)
 - $-z_i = \alpha x_i + (1 \alpha) y_i$ where $\alpha : 0 \le \alpha \le 1$.
 - The parameter α can be:
 - constant: uniform arithmetical crossover
 - variable (e.g. depend on the age of the population)
 - picked at random every time

Real-Valued or Floating-Point Representation: Single arithmetic crossover

- Parents: $\langle x_1, \dots, x_n \ \rangle$ and $\langle y_1, \dots, y_n \rangle$
- Pick a single gene (k) at random,
- child₁ is: $\langle x_1, ..., x_k, \alpha \cdot y_k + (1 \alpha) \cdot x_k, ..., x_n \rangle$
- Reverse for other child. e.g. with α = 0.5

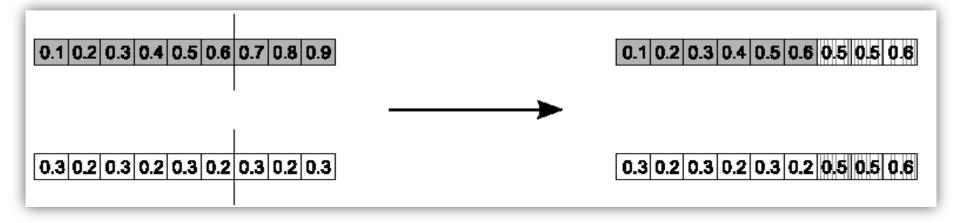

Real-Valued or Floating-Point Representation: Simple arithmetic crossover

- Parents: $\langle x_1, ..., x_n \rangle$ and $\langle y_1, ..., y_n \rangle$
- Pick a random gene (k) after this point mix values

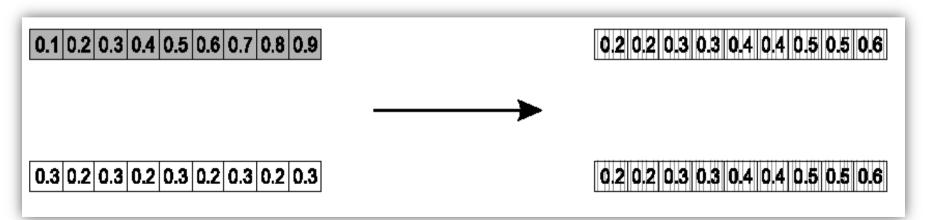

• child₁ is:

$$\langle x_1, ..., x_k, \alpha \cdot y_{k+1} + (1-\alpha) \cdot x_{k+1}, ..., \alpha \cdot y_n + (1-\alpha) \cdot x_n \rangle$$

Real-Valued or Floating-Point Representation: Whole arithmetic crossover

- Most commonly used
- Parents: $\langle x_1, \dots, x_n \rangle$ and $\langle y_1, \dots, y_n \rangle$
- Child₁ is: $a \cdot \overline{x} + (1 a) \cdot \overline{y}$
- reverse for other child. e.g. with α = 0.5

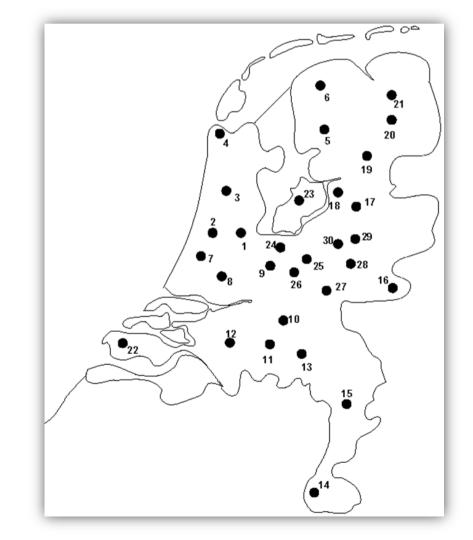

Permutation Representations

- Ordering/sequencing problems form a special type
- Task is (or can be solved by) arranging some objects in a certain order. Examples:
 - production scheduling: important thing is which elements are scheduled before others (order)
 - Travelling Salesman Problem (TSP) : important thing is which elements occur next to each other (<u>adjacency</u>)
- These problems are generally expressed as a permutation:
 - if there are *n* variables then the representation is as a list of *n* integers, each of which occurs exactly once

Permutation Representation: TSP example

- Problem:
 - Given n cities
 - Find a complete tour with minimal length
- Encoding:
 - Label the cities 1, 2, ... , *n*
 - One complete tour is one permutation (e.g. for n =4 [1,2,3,4], [3,4,2,1] are OK)
- Search space is BIG: for 30 cities there are 30! ≈ 10³² possible tours

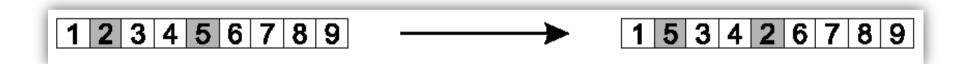

Permutation Representations: Mutation

- Normal mutation operators lead to inadmissible solutions
 - e.g. bit-wise mutation: let gene *i* have value *j*
 - changing to some other value k would mean that k occurred twice and j no longer occurred
- Therefore must change at least two values
- Mutation parameter now reflects the probability that some operator is applied once to the whole string, rather than individually in each position

Permutation Representations: Swap mutation

Pick two alleles at random and swap their positions

Permutation Representations: Insert Mutation

- Pick two allele values at random
- Move the second to follow the first, shifting the rest along to accommodate
- Note that this preserves most of the order and the adjacency information

Permutation Representations: Scramble mutation

- Pick a subset of genes at random
- Randomly rearrange the alleles in those positions

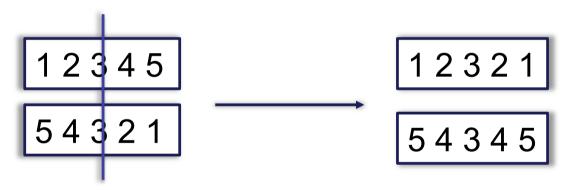

Permutation Representations: Inversion mutation

- Pick two alleles at random and then invert the substring between them.
- Preserves most adjacency information (only breaks two links) but disruptive of order information

Permutation Representations: Crossover operators

 "Normal" crossover operators will often lead to inadmissible solutions

 Many specialised operators have been devised which focus on combining order or adjacency information from the two parents

Permutation Representations: Order 1 crossover (1/2)

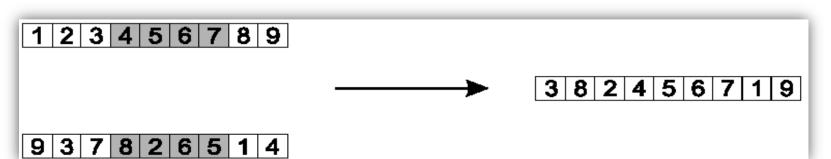

- Idea is to preserve relative order that elements occur
- Informal procedure:
 - 1. Choose an arbitrary part from the first parent
 - 2. Copy this part to the first child
 - 3. Copy the numbers that are not in the first part, to the first child:
 - starting right from cut point of the copied part,
 - using the **order** of the second parent
 - and wrapping around at the end
 - 4. Analogous for the second child, with parent roles reversed

Permutation Representations: Order 1 crossover (2/2)

Copy randomly selected set from first parent

• Copy rest from second parent in order 1,9,3,8,2

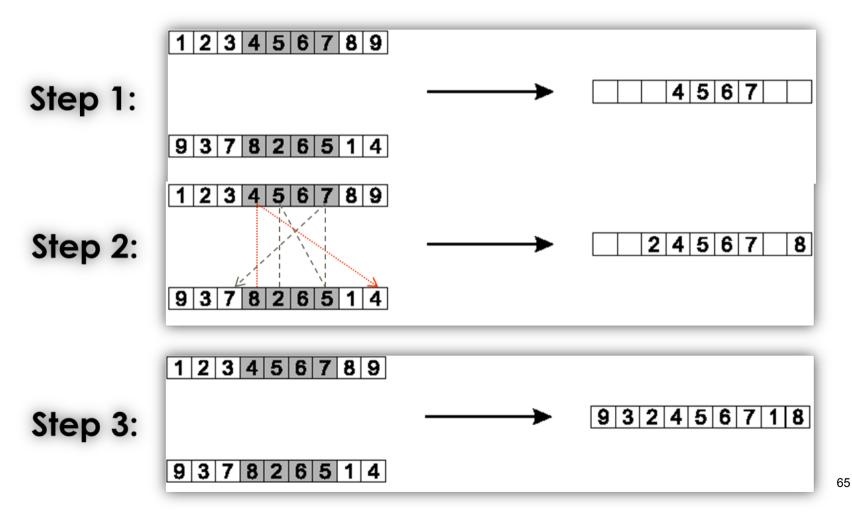

Permutation Representations: Partially Mapped Crossover (PMX) (1/2)

Informal procedure for parents P1 and P2:

- 1. Choose random segment and copy it from P1
- 2. Starting from the first crossover point look for elements in that segment of P2 that have not been copied
- 3. For each of these *i* look in the offspring to see what element *j* has been copied in its place from P1
- 4. Place *i* into the position occupied *j* in P2, since we know that we will not be putting *j* there (as is already in offspring)
- 5. If the place occupied by *j* in P2 has already been filled in the offspring *k*, put *i* in the position occupied by *k* in P2
- 6. Having dealt with the elements from the crossover segment, the rest of the offspring can be filled from P2.

Second child is created analogously

Permutation Representations: Partially Mapped Crossover (PMX) (2/2)

Permutation Representations: Cycle crossover (1/2)

Basic idea:

Each allele comes from one parent *together with its position*.

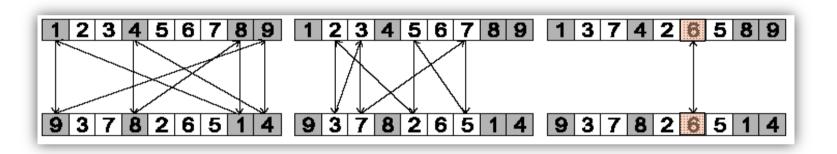

Informal procedure:

- 1. Make a cycle of alleles from P1 in the following way.
 - (a) Start with the first allele of P1.
 - (b) Look at the allele at the same position in P2.
 - (c) Go to the position with the *same allele* in P1.
 - (d) Add this allele to the cycle.
 - (e) Repeat step b through d until you arrive at the first allele of P1.
- 2. Put the alleles of the cycle in the first child on the positions they have in the first parent.
- 3. Take next cycle from second parent

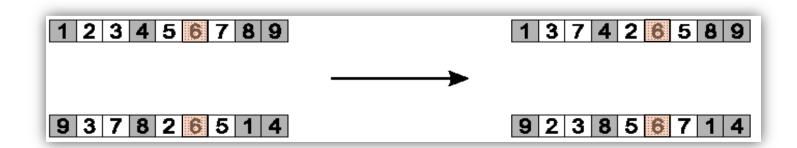

Permutation Representations: Cycle crossover (2/2)

• Step 1: identify cycles

1 2 3 4 5 6 7 8 9

• Step 2: copy alternate cycles into offspring

Permutation Representations: Edge Recombination (1/3)

- Works by constructing a table listing which edges are present in the two parents, if an edge is common to both, mark with a +
- e.g. [1 2 3 4 5 6 7 8 9] and [9 3 7 8 2 6 5 1 4]

Element	Edges	Element	Edges
1	$2,\!5,\!4,\!9$	6	2,5+,7
2	$1,\!3,\!6,\!8$	7	$3,\!6,\!8+$
3	$2,\!4,\!7,\!9$	8	2,7+,9
4	$1,\!3,\!5,\!9$	9	$1,\!3,\!4,\!8$
5	$1,\!4,\!6+$		

Permutation Representations: Edge Recombination (2/3)

Informal procedure: once edge table is constructed

- 1. Pick an initial element, *entry*, at random and put it in the offspring
- 2. Set the variable *current element* = *entry*
- 3. Remove all references to *current element* from the table
- 4. Examine list for current element:
 - If there is a common edge, pick that to be next element
 - Otherwise pick the entry in the list which itself has the shortest list
 - Ties are split at random
- 5. In the case of reaching an empty list:
 - a new element is chosen at random

Permutation Representations: Edge Recombination (3/3)

Element	Edges	Element	Edges
1	$2,\!5,\!4,\!9$	6	2,5+,7
2	$1,\!3,\!6,\!8$	7	3,6,8+
3	$2,\!4,\!7,\!9$	8	2,7+,9
4	$1,\!3,\!5,\!9$	9	1,3,4,8
5	1,4,6+		

Choices	Element	Reason	Partial
	selected		result
All	1	Random	[1]
$2,\!5,\!4,\!9$	5	Shortest list	$[1 \ 5]$
$4,6 \\ 2,7$	6	Common edge	[1 5 6]
2,7	2	Random choice (both have two items in list)	[1 5 6 2]
3,8	8	Shortest list	[1 5 6 2 8]
7,9	7	Common edge	[156287]
3	3	Only item in list	[1562873]
4,9	9	Random choice	$[1\ 5\ 6\ 2\ 8\ 7\ 3\ 9]$
4	4	Last element	$[1\ 5\ 6\ 2\ 8\ 7\ 3\ 9\ 4\]$

Tree Representation (1/5)

Trees are a universal form, e.g. consider

• Arithmetic formula:
$$2 \cdot \pi + \left((x+3) - \frac{y}{5+1} \right)$$

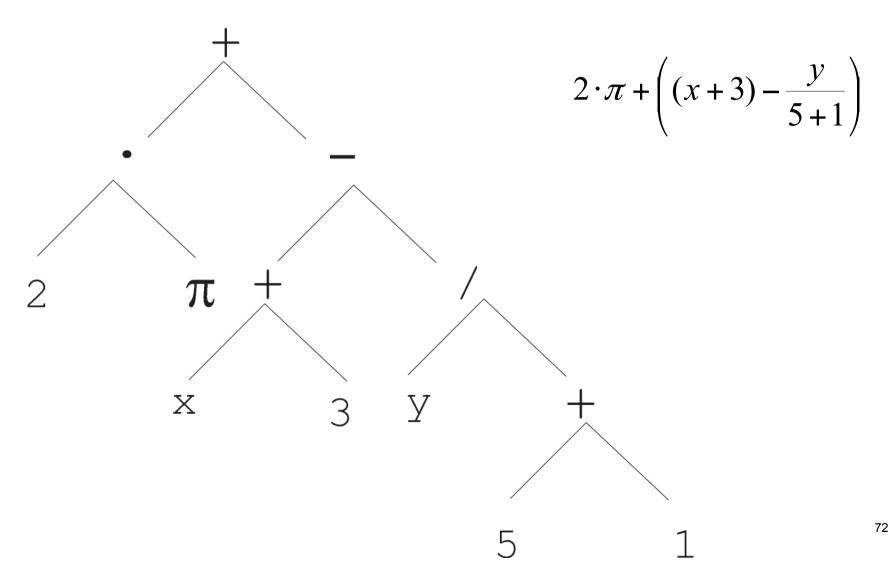

• Logical formula: $(x \land true) \rightarrow ((x \lor y) \lor (z \Leftrightarrow (x \land y)))$ i =1; while (i < 20){

}

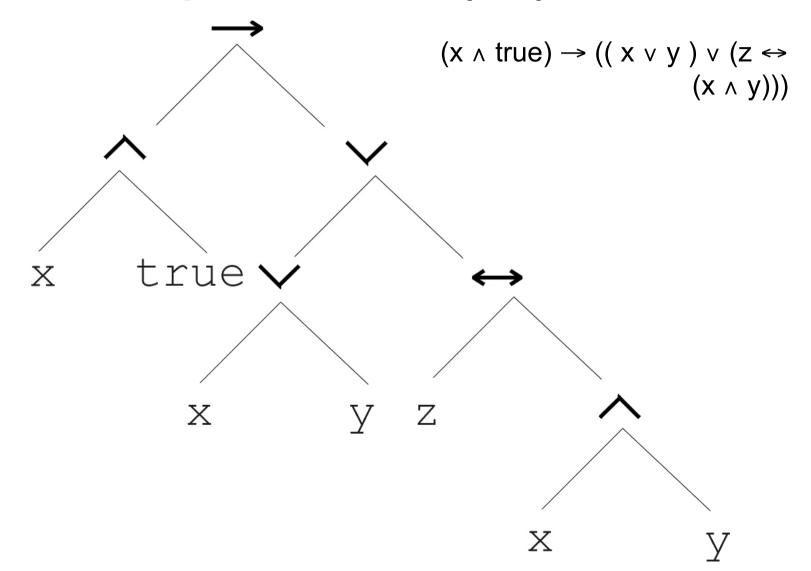

i = i +1

• Program:

Tree Representation (2/5)

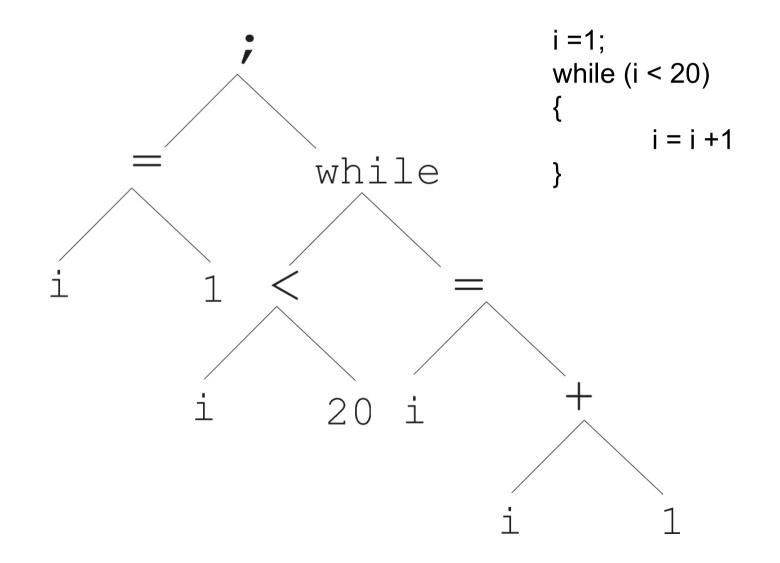

Tree Representation (3/5)

73

Tree Representation (4/5)

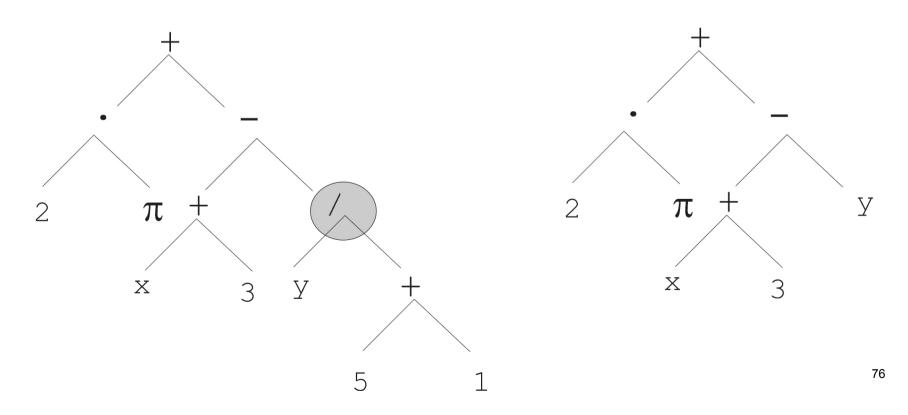

74

Tree Representation (5/5)

- In GA, ES, EP chromosomes are linear structures (bit strings, integer string, realvalued vectors, permutations)
- Tree shaped chromosomes are non-linear structures
- In GA, ES, EP the size of the chromosomes is fixed
- Trees in GP may vary in depth and width

Tree Representation: Mutation (1/2)

• Most common mutation: replace randomly chosen subtree by randomly generated tree

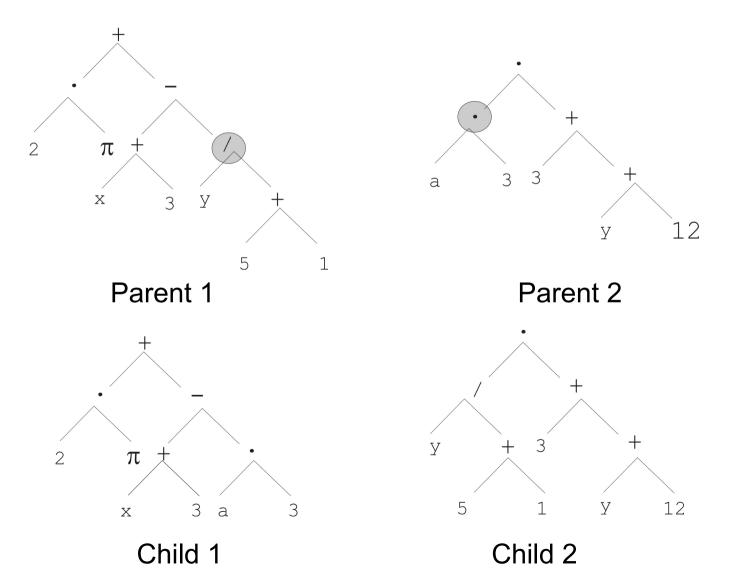

Tree Representation: Mutation (2/2)

- Mutation has two parameters:
 - Probability p_m to choose mutation
 - Probability to chose an internal point as the root of the subtree to be replaced
- Remarkably p_m is advised to be 0 (Koza'92) or very small, like 0.05 (Banzhaf et al. '98)
- The size of the child can exceed the size of the parent

Tree Representation: Recombination (1/2)

- Most common recombination: exchange two randomly chosen subtrees among the parents
- Recombination has two parameters:
 - Probability p_c to choose recombination
 - Probability to chose an internal point within each parent as crossover point
- The size of offspring can exceed that of the parents

Tree Representation: Recombination (2/2)

79
