INF3490 - Biologically inspired computing

Lecture 2: Eiben and Smith, chapter 1-4

Evolutionary Algorithms - Introduction and representation

Jim Tørresen

UiO: Department of Informatics

Evolution in Nature

- A population of individuals exists in an environment with limited resources
- Competition for those resources causes selection of those fitter individuals that are better adapted to the environment
- These individuals act as seeds for the generation of new individuals through recombination and mutation
- The new individuals have their fitness evaluated and compete (possibly also with parents) for survival.
- Over time Natural selection causes a rise in the fitness of the population

UiO Department of Informatics

Evolution

• Biological evolution:

- Lifeforms adapt to a particular environment over successive generations.
- Combinations of traits that are better adapted tend to increase representation in population.
- Mechanisms: Selection+Crossover, Mutation and Survival of the fittest.

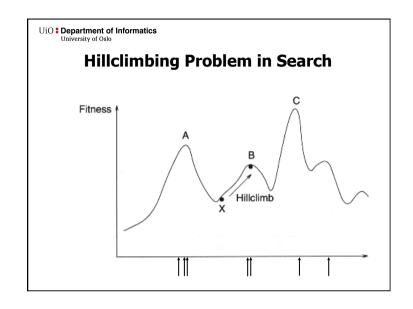

Evolutionary Computing (EC):

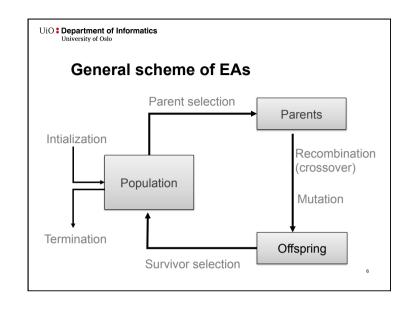

- Mimic the biological evolution to optimize solutions to a wide variety of complex problems.
- In every new generation, a new set of solutions is created using bits and pieces of the fittest of the old.

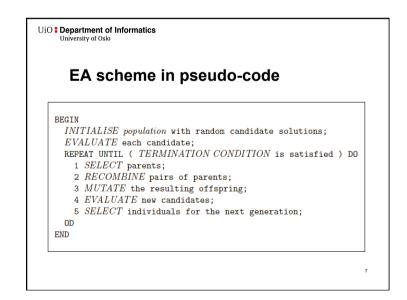

UiO Department of Informatics

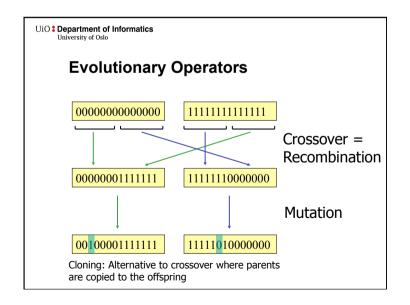

Evolutionary Algorithms (EAs)

- EAs fall into the category of "generate and test" algorithms
- · They are stochastic, population-based algorithms
- Variation operators (recombination and mutation) create the necessary diversity and thereby facilitate novelty
- Selection reduces diversity and acts as a force pushing quality

Scheme of an EA: Common model of evolutionary processes

- Population of individuals
- Individuals have a fitness
- · Variation operators: crossover, mutation
- Selection towards higher fitness
 - "survival of the fittest" and
 - "mating of the fittest"

Optimization according to some fitness-criterion (optimization on a fitness landscape)

9

UiO : Department of Informatics University of Oslo Representation: EA terms locus: the position of a gene allele= 0 or 1 (what values a gene can have) Chromosome (array 0 datatype) gene: one element of genotype: a set of gene the array values (data variable) phenotype: what could be built/developed based on the genotype

UiO : Department of Informatics

Scheme of an EA: Two pillars of evolution

There are two competing forces

Increasing population diversity by genetic operators

- mutation
- recombination

Push towards novelty

Decreasing population **diversity** by selection

- of parents
- of survivors

Push towards quality

10

UiO Department of Informatics
University of Oslo

Main EA components: Evaluation (fitness) function

- Role:
 - Represents the task to solve, the requirements to adapt to (can be seen as "the environment")
 - Enables selection (provides basis for comparison)
 - e.g., some phenotypic traits are advantageous, desirable,
 e.g. big ears cool better, these traits are rewarded by more offspring that will expectedly carry the same trait
- A.k.a. quality function or objective function
- Assigns a single real-valued fitness to each phenotype which forms the basis for selection
- · Typically we talk about fitness being maximised
 - Some problems may be best posed as minimisation problems, but conversion is trivial

Main EA components: Population

- Role: holds **the candidate solutions** of the problem as individuals (genotypes)
- Formally, a population is a multiset of individuals, i.e. repetitions are possible
- Population is the basic unit of evolution, i.e., the population is evolving, not the individuals
- Selection operators act on population level
- · Variation operators act on individual level

13

UiO ♣ Department of Informatics
University of Oslo

Main EA components:
Selection mechanism (2/3)

Example: roulette wheel selection

fitness(A) = 3
fitness(B) = 1
fitness(C) = 2

In principle, any selection mechanism can be used for parent selection as well as for survivor selection

UiO Department of Informatics

Main EA components: Selection mechanism (1/3)

Role:

- · Identifies individuals
 - to become parents
 - to survive
- Pushes population towards higher fitness
- Usually probabilistic
 - high quality solutions more likely to be selected than low quality
 - but not guaranteed
 - even worst in current population usually has non-zero probability of being selected
- This stochastic nature can aid escape from local optima 14

UiO Department of Informatics

Main EA components: Selection mechanism (3/3)

- · Survivor selection a.k.a. replacement
- Most EAs use fixed population size so need a way of going from (parents + offspring) to next generation
- Often deterministic (while parent selection is usually stochastic)
 - Fitness based: e.g., rank parents + offspring and take hest
 - Age based: make as many offspring as parents and delete all parents
- Sometimes a combination of stochastic and deterministic (elitism)

ь

Main EA components: What are the different types of EAs

- Historically different flavours of EAs have been associated with different data types to represent solutions
 - Binary strings : Genetic Algorithms (GA)
 - Real-valued vectors : Evolution Strategies (ES)
 - Finite state Machines: Evolutionary Programming (EP)
 - LISP trees: Genetic Programming (GP)
- These differences are largely irrelevant, best strategy
 - choose representation to suit problem
 - choose variation operators to suit representation
- Selection operators only use fitness and so are independent of representation

17

UiO Department of Informatics

Main EA components: Mutation (1/2)

- · Role: causes small, random variance
- · Acts on one genotype and delivers another
- Element of randomness is essential and differentiates it from other unary heuristic operators
- Importance ascribed depends on representation and historical dialect:
 - Binary GAs background operator responsible for preserving and introducing diversity
 - EP for FSM's / continuous variables the only search operator
 - GP hardly used
- May guarantee connectedness of search space and hence convergence proofs

UiO Department of Informatics

Main EA components: Variation operators

- Role: to generate new candidate solutions
- Usually divided into two types according to their arity (number of inputs to the variation operator):
 - Arity 1: **mutation** operators
 - Arity >1 : recombination operators
 - Arity = 2 typically called **crossover**
 - Arity > 2 is formally possible, seldom used in EC
- There has been much debate about relative importance of recombination and mutation
 - Nowadays most EAs use both
 - Variation operators must match the given representation

UiO: Department of Informatics
University of Oslo

Main EA components:
Mutation (2/2)

before 1 1 1 1 1 1 1 1

after 1 1 1 0 1 1 1

Main EA components: Recombination (1/2)

- · Role: merges information from parents into offspring
- · Choice of what information to merge is stochastic
- Most offspring may be worse, or the same as the parents
- Hope is that some are better by combining elements of genotypes that lead to good traits
- Principle has been used for millennia by breeders of plants and livestock

21

UiO Department of Informatics

Main EA components: Initialisation / Termination

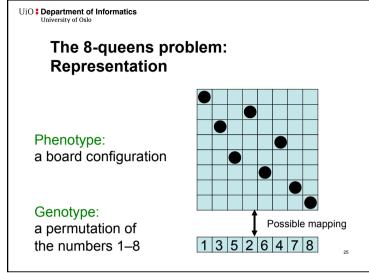

- · Initialisation usually done at random,
 - Need to ensure even spread and mixture of possible allele values
 - Can include existing solutions, or use problem-specific heuristics, to "seed" the population
- Termination condition checked every generation
 - Reaching some (known/hoped for) fitness
 - Reaching some maximum allowed number of generations
 - Reaching some minimum level of diversity
 - Reaching some specified number of generations without fitness improvement

UiO: Department of Informatics
University of Oslo

Example:
The 8-queens problem

Place 8 queens on an 8x8 chessboard in such a way that they cannot check each other

24

The 8-queens problem: Fitness evaluation

- Penalty of one queen: the number of queens she can check
- Penalty of a configuration: the sum of penalties of all gueens
- · Note: penalty is to be minimized
- Fitness of a configuration: inverse penalty to be maximized

UiO : Department of Informatics University of Oslo The 8-queens problem: Mutation Small variation in one permutation, e.g.: • swapping values of two randomly chosen positions, $1 \mid 3 \mid 5 \mid 2 \mid 6 \mid 4 \mid 7 \mid 8 \longrightarrow 1 \mid 3 \mid 7 \mid 2 \mid 6 \mid 4 \mid 5 \mid 8$ UiO : Department of Informatics University of Oslo

The 8-queens problem: Recombination

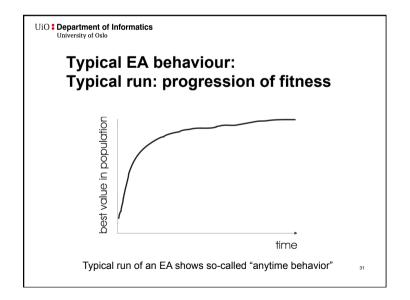

Combining two permutations into two new permutations:

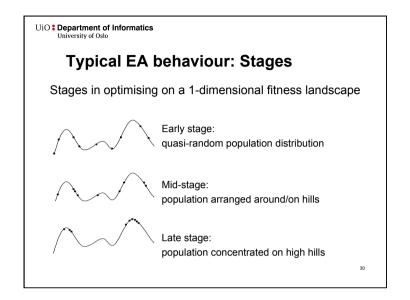

- · choose random crossover point
- · copy first parts into children
- create second part by inserting values from other parent:
 - in the order they appear there
 - · beginning after crossover point
 - · skipping values already in child

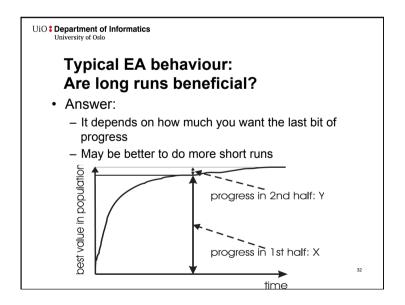

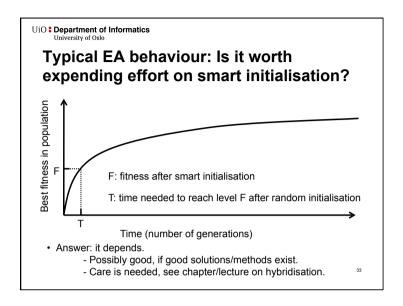

The 8-queens problem: Selection

- · Parent selection:
 - Pick 5 parents and take best two to undergo crossover
- Survivor selection (replacement)
 - When inserting a new child into the population, choose an existing member to replace by:
 - sorting the whole population by decreasing fitness
 - enumerating this list from high to low
 - replacing the first with a fitness lower than the given child

Typical EA behaviour: EAs and domain knowledge

- Trend in the 90's: adding problem specific knowledge to EAs (special variation operators, repair, etc)
- Result: EA performance curve "deformation":
 - better on problems of the given type
 - worse on problems different from given type
 - amount of added knowledge is variable
- Recent theory suggests the search for an "allpurpose" algorithm may be fruitless

UiO : Department of Informatics University of Oslo

Typical EA behaviour: Evolutionary Algorithms in context

- There are many views on the use of EAs as robust problem solving tools
- For most problems a problem-specific tool may:
 - perform better than a generic search algorithm on most instances.
 - have limited utility => not do well on all instances
- · Goal is to provide robust tools that provide:
 - evenly good performance over a range of problems and instances

34

UiO : Department of Informatics University of Oslo

Chapter 4: Representation, Mutation, and Recombination

- Role of representation and variation operators
- Most common representation of genomes:
 - Binary
 - Integer
 - Real-Valued or Floating-Point
 - Permutation
 - Tree

36

Role of representation and variation operators

- · First stage of building an EA and most difficult one: choose right representation for the problem
- · Variation operators: mutation and crossover
- Type of variation operators needed depends on chosen representation
- TSP problem
 - What are possible representations?

UiO: Department of Informatics **Binary Representation** · One of the earliest representations · Genotype consists of a string of binary digits Phenotype space Genotype space = Encodina (representation) 10010001 10010010 010001001 011101001 Decodina (inverse representation)

UiO : Department of Informatics **Binary Representation:** Mutation • Alter each gene independently with a probability p_m • p_m is called the mutation rate - Typically between 1/pop size and 1/ chromosome length 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 0 1 0 0 1 0 1 1 0 0 0 1 0 1 1 0 0 1 child

UiO : Department of Informatics **Binary Representation:** 1-point crossover • Choose a random point on the two parents Split parents at this crossover point · Create children by exchanging tails • P_c typically in range (0.6, 0.9) 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 parents 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 0 0 0 0 0 1 1 1 1 1 1 1 1 1 1 1 1 1 children 1 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0

Binary Representation: Alternative Crossover Operators

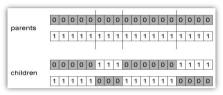

- Why do we need other crossover(s)?
- Performance with 1-point crossover depends on the order that variables occur in the representation
 - More likely to keep together genes that are near each other
 - Can never keep together genes from opposite ends of string
 - This is known as Positional Bias
 - Can be exploited if we know about the structure of our problem, but this is not usually the case

41

UiO • Department of Informatics University of Oslo

Binary Representation: n-point crossover

- · Choose n random crossover points
- · Split along those points
- Glue parts, alternating between parents
- Generalisation of 1-point (still some positional bias)

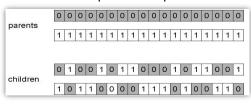

42

UiO Department of Informatics

Binary Representation: Uniform crossover

- · Assign 'heads' to one parent, 'tails' to the other
- · Flip a coin for each gene of the first child
- Make an inverse copy of the gene for the second child
- · Inheritance is independent of position

UiO : Department of Informatics University of Oslo

Binary Representation: Crossover OR mutation? (1/3)

- · Decade long debate:
 - which one is better / necessary?
- Answer (at least, rather wide agreement):
 - it depends on the problem, but
 - in general, it is good to have both
 - both have a different role
 - mutation-only-EA is possible, x-over-only-EA would not work

Binary Representation: Crossover OR mutation? (2/3)

Exploration: Discovering promising areas in the search space, i.e. gaining information on the problem

Exploitation: Optimising within a promising area, i.e. using information

There is co-operation AND competition between them:

- Crossover is explorative, it makes a big jump to an area somewhere "in between" two (parent) areas
- **Mutation** is **exploitative**, it creates random *small* diversions, thereby staying near (in the area of) the parent

UiO : Department of Informatics University of Oslo

Integer Representation

- Nowadays it is generally accepted that it is better to encode numerical variables directly (integers, floating point variables)
- Some problems naturally have integer variables, e.g. image processing parameters
- Others take categorical values from a fixed set e.g. {blue, green, yellow, pink}
- N-point / uniform crossover operators work
- Extend bit-flipping mutation to make
 - "creep" i.e. more likely to move to similar value
 - Adding a small (positive or negative) value to each gene with probability p
 - Random resetting (esp. categorical variables)
 - With probability p_m a new value is chosen at random
- · Same recombination as for binary representation

47

UiO Department of Informatics

Binary Representation: Crossover OR mutation? (3/3)

- Only crossover can combine information from two parents
- Only mutation can introduce new information (alleles)
- To hit the optimum you often need a 'lucky' mutation

46

UiO: Department of Informatics

Real-Valued or Floating-Point Representation: Uniform Mutation

· General scheme of floating point mutations

$$\bar{x} = \langle x_1, ..., x_l \rangle \rightarrow \bar{x}' = \langle x_1', ..., x_l' \rangle$$

$$x_i, x_i' \in [LB_i, UB_i]$$

Uniform Mutation

 x'_i drawn randomly (uniform) from $[LB_i, UB_i]$

Analogous to bit-flipping (binary) or random resetting (integers)

Real-Valued or Floating-Point Representation: Nonuniform Mutation

- Non-uniform mutations:
 - Many methods proposed, such as time-varying range of change etc.
 - Most schemes are probabilistic but usually only make a small change to value
 - Most common method is to add random deviate to each variable separately, taken from $N(0, \sigma)$ Gaussian distribution and then curtail to range $x'_i = x_i + N(0,\sigma)$
 - Standard deviation σ, mutation step size, controls amount of change (2/3 of drawings will lie in range (- σ to $+ \sigma$)

UiO: Department of Informatics

Real-Valued or Floating-Point Representation: **Crossover operators**

- Discrete:
 - each allele value in offspring z comes from one of its parents (x, y) with equal probability: $z_i = x_i$ or y_i
 - Could use n-point or uniform
- Intermediate
 - exploits idea of creating children "between" parents (hence a.k.a. arithmetic recombination)
 - $-z_i = \alpha x_i + (1 \alpha) y_i$ where $\alpha : 0 \le \alpha \le 1$.
 - The parameter α can be:
 - constant: uniform arithmetical crossover
 - variable (e.g. depend on the age of the population)
 picked at random every time

UiO : Department of Informatics University of Oslo

Real-Valued or Floating-Point Representation: Single arithmetic crossover

- Parents: $\langle x_1,...,x_n \rangle$ and $\langle y_1,...,y_n \rangle$
- Pick a single gene (k) at random,
- child₁ is: $\langle x_1, ..., x_k, \alpha \cdot y_k + (1-\alpha) \cdot x_k, ..., x_n \rangle$
- Reverse for other child. e.g. with α = 0.5

UiO : Department of Informatics University of Oslo

Real-Valued or Floating-Point Representation: Simple arithmetic crossover

- Parents: $\langle x_1,...,x_n \rangle$ and $\langle y_1,...,y_n \rangle$
- Pick a random gene (k) after this point mix values
- child₁ is:

$$\langle x_1, ..., x_k, \alpha \cdot y_{k+1} + (1-\alpha) \cdot x_{k+1}, ..., \alpha \cdot y_n + (1-\alpha) \cdot x_n \rangle$$

Real-Valued or Floating-Point Representation:

Whole arithmetic crossover

- Most commonly used
- Parents: $\langle x_1,...,x_n \rangle$ and $\langle y_1,...,y_n \rangle$
- Child₁ is:

$$a \cdot \overline{x} + (1 - a) \cdot \overline{y}$$

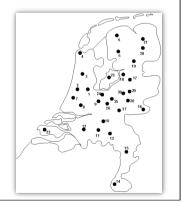

• reverse for other child. e.g. with α = 0.5

0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9		0.2 0.2 0.3 0.3 0.4 0.4 0.5 0.5 0.6	
			
0.3 0.2 0.3 0.2 0.3 0.2 0.3 0.2 0.3		0.2 0.2 0.3 0.3 0.4 0.4 0.5 0.5 0.6	

UiO Department of Informatics

Permutation Representation: TSP example

- · Problem:
 - · Given n cities
 - Find a complete tour with minimal length
- · Encoding:
 - Label the cities 1, 2, ..., n
 - One complete tour is one permutation (e.g. for n =4 [1,2,3,4], [3,4,2,1] are OK)
- Search space is BIG: for 30 cities there are 30! ≈ 10³² possible tours

UiO : Department of Informatics
University of Oslo

Permutation Representations

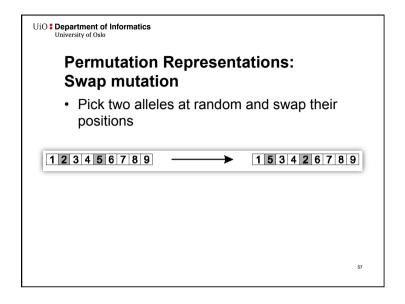

- · Ordering/sequencing problems form a special type
- Task is (or can be solved by) arranging some objects in a certain order. Examples:
 - production scheduling: important thing is which elements are scheduled before others (<u>order</u>)
 - Travelling Salesman Problem (TSP): important thing is which elements occur next to each other (<u>adjacency</u>)
- These problems are generally expressed as a permutation:
 - if there are n variables then the representation is as a list of n integers, each of which occurs exactly once

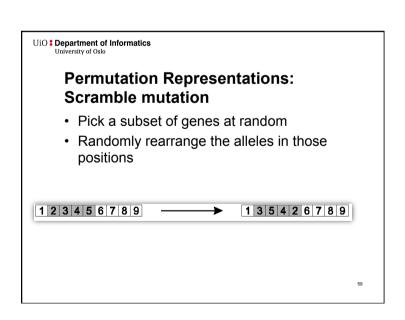

54

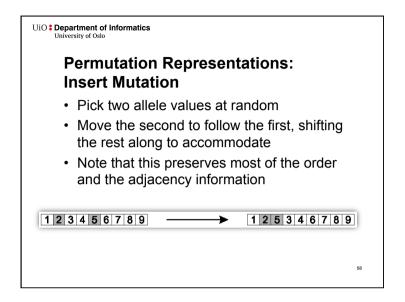

UiO Department of Informatics

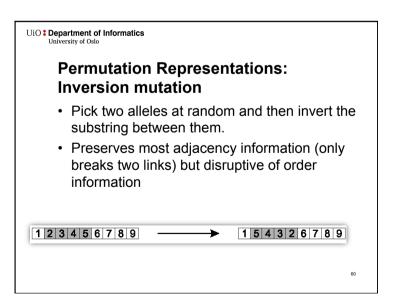

Permutation Representations: Mutation

- Normal mutation operators lead to inadmissible solutions
 - e.g. bit-wise mutation: let gene *i* have value *j*
 - changing to some other value k would mean that k occurred twice and j no longer occurred
- Therefore must change at least two values
- Mutation parameter now reflects the probability that some operator is applied once to the whole string, rather than individually in each position

Permutation Representations: Crossover operators

 "Normal" crossover operators will often lead to inadmissible solutions

 Many specialised operators have been devised which focus on combining order or adjacency information from the two parents

61

UiO • Department of Informatics University of Oslo

Permutation Representations: Order 1 crossover (1/2)

- Idea is to preserve relative order that elements occur
- Informal procedure:
 - 1. Choose an arbitrary part from the first parent
 - 2. Copy this part to the first child
 - 3. Copy the numbers that are not in the first part, to the first child:
 - · starting right from cut point of the copied part,
 - · using the order of the second parent
 - · and wrapping around at the end
 - 4. Analogous for the second child, with parent roles reversed

62

UiO: Department of Informatics University of Oslo Permutation Representations: Order 1 crossover (2/2)

Copy randomly selected set from first parent

 Copy rest from second parent in order 1,9,3,8,2

123456789		
	→	3 8 2 4 5 6 7 1 9
937826514		

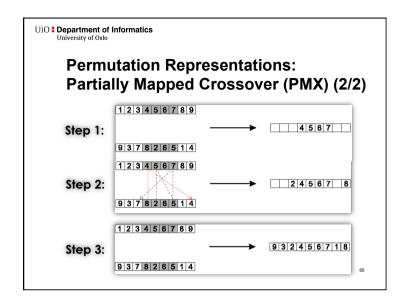

UiO: Department of Informatics

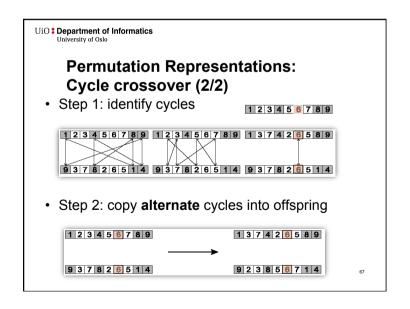

Permutation Representations: Partially Mapped Crossover (PMX) (1/2)

Informal procedure for parents P1 and P2:

- 1. Choose random segment and copy it from P1
- Starting from the first crossover point look for elements in that segment of P2 that have not been copied
- For each of these i look in the offspring to see what element j has been copied in its place from P1
- Place i into the position occupied j in P2, since we know that we will not be putting j there (as is already in offspring)
- If the place occupied by j in P2 has already been filled in the offspring k, put i in the position occupied by k in P2
- Having dealt with the elements from the crossover segment, the rest of the offspring can be filled from P2.

Second child is created analogously

Permutation Representations: Cycle crossover (1/2)

Basic idea:

Each allele comes from one parent *together with its position*.

Informal procedure:

- 1. Make a cycle of alleles from P1 in the following way.
 - (a) Start with the first allele of P1.
 - (b) Look at the allele at the same position in P2.
 - (c) Go to the position with the same allele in P1.
 - (d) Add this allele to the cycle.
 - (e) Repeat step b through d until you arrive at the first allele of P1.
- 2. Put the alleles of the cycle in the first child on the positions they have in the first parent.
- 3. Take next cycle from second parent

66

UiO Department of Informatics

Permutation Representations: Edge Recombination (1/3)

- Works by constructing a table listing which edges are present in the two parents, if an edge is common to both, mark with a +
- e.g. [1 2 3 4 5 6 7 8 9] and [9 3 7 8 2 6 5 1 4]

Element	Edges	Element	Edges
1	2,5,4,9	6	2,5+,7
2	1,3,6,8	7	3,6,8+
3	2,4,7,9	8	2,7+,9
4	1,3,5,9	9	1,3,4,8
5	1,4,6+		

Permutation Representations: Edge Recombination (2/3)

Informal procedure: once edge table is constructed

- Pick an initial element, entry, at random and put it in the offspring
- 2. Set the variable *current element* = *entry*
- 3. Remove all references to current element from the table
- 4. Examine list for current element:
 - If there is a common edge, pick that to be next element
 - Otherwise pick the entry in the list which itself has the shortest list
 - Ties are split at random
- 5. In the case of reaching an empty list:
 - a new element is chosen at random

69

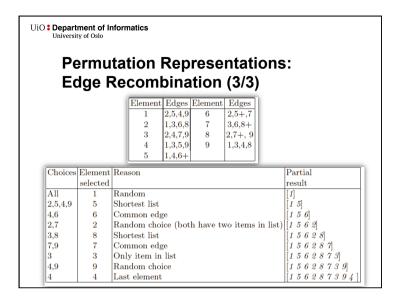

UiO Department of Informatics

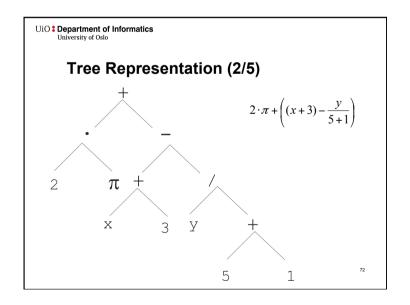

Tree Representation (1/5)

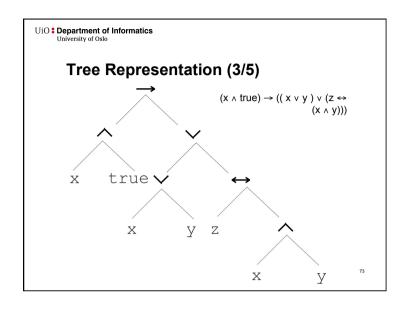

- Trees are a universal form, e.g. consider
- Arithmetic formula: $2 \cdot \pi + \left((x+3) \frac{y}{5+1} \right)$
- Logical formula: $(x \land true) \rightarrow ((x \lor y) \lor (z \leftrightarrow (x \land y)))$

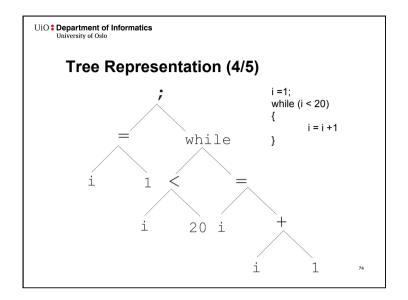

i =1; while (i < 20)

• Program: while (1 < 20) { i = i +1

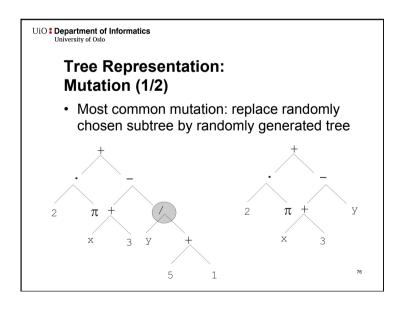

UiO : Department of Informatics
University of Oslo

Tree Representation (5/5)

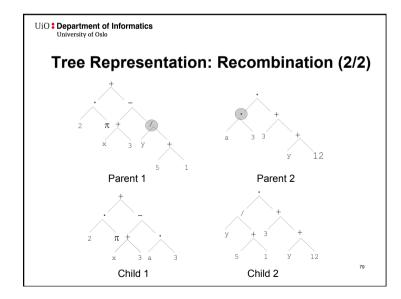

- In GA, ES, EP chromosomes are linear structures (bit strings, integer string, real-valued vectors, permutations)
- Tree shaped chromosomes are non-linear structures
- In GA, ES, EP the size of the chromosomes is fixed
- · Trees in GP may vary in depth and width

Tree Representation: Mutation (2/2)

- Mutation has two parameters:
 - Probability p_m to choose mutation
 - Probability to chose an internal point as the root of the subtree to be replaced
- Remarkably p_m is advised to be 0 (Koza'92) or very small, like 0.05 (Banzhaf et al. '98)
- The size of the child can exceed the size of the parent

77

UiO Department of Informatics

Tree Representation: Recombination (1/2)

- Most common recombination: exchange two randomly chosen subtrees among the parents
- Recombination has two parameters:
 - Probability p_c to choose recombination
 - Probability to chose an internal point within each parent as crossover point
- The size of offspring can exceed that of the parents
