A Quick Overview

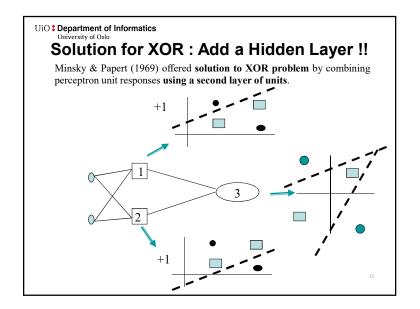

- Linear Models are easy to understand.
- However, they are very simple.
 - They can only identify flat decision boundaries (straight lines, planes, hyperplanes, ...).
- Majority of interesting data are not linearly separable. Then?

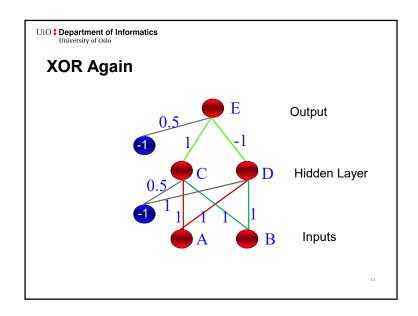

A Quick Overview

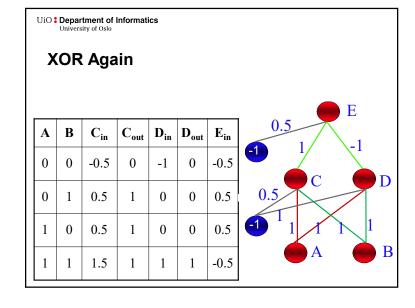

- **Learning** in the neural networks (NN) happens in the weights.
- Weights are associated with connections.
- Thus, it is sensible to add more connections to perform more complex computations.
- Two ways for non-lin. separation (not exclusive):
 - Recurrent Network: connect the output neurons to the inputs with feedback connections.
 - Multi-layer perceptron network: add neurons between the input nodes and the outputs.

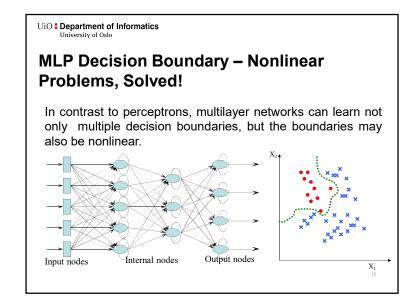

Multilayer Network Structure

- A neural network with one or **more** layers of **nodes** between the input and the output nodes is called **multilayer network**.
- The multilayer network structure, or architecture, or topology, consists of an input layer, one or more hidden layers, and one output layer.
- The input nodes pass values to the first hidden layer, its nodes to the second and so until producing outputs.
 - A network with a layer of input units, a layer of hidden units and a layer of output units is a *two-layer network*.
 - A network with two layers of hidden units is a *three-layer network*, and so on.

Properties of the Multi-Layer Perceptron

- · No connections within a single layer.
- No direct connections between input and output layers.
- Fully connected; all nodes in one layer connect to all nodes in the next layer.
- Number of output units need not equal number of input units.
- Number of hidden units per layer can be more or less than input or output units.

UiO Department of Informatics

Then...

The problem is: How to train Multi Layer Perceptrons??

Solution: Backpropagation Algorithm (Rumelhart and colleagues, 1986)

UiO Department of Informatics

How to Train MLP?

- How we can train the network, so that
 - The weights are adapted to generate correct (target answer)?
- In Perceptron, errors are computed at the output.
- In MLP,
 - Don't know which weights are wrong:
 - Don't know the correct activations for the neurons in the hidden layers.

UiO: Department of Informatics
University of Oslo

Rumelhart, Hinton and Williams (1986) (though actually invented earlier in a PhD thesis relating to economics)

Backward step: propagate errors from output to hidden layer

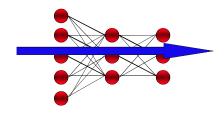

V_{ki}

Forward step: Propagate activation from input to output layer

Training MLPs

Forward Pass

- 1. Put the input values in the input layer.
- 2. Calculate the activations of the hidden nodes.
- 3. Calculate the activations of the output nodes.

21

UiO: Department of Informatics

Error Function

- Single scalar function for entire network.
- Parameterized by weights (objects of interest).
- Multiple errors of different signs should not cancel out.
- Sum-of-squares error:

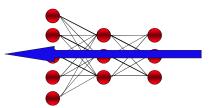

$$E(\mathbf{w}) = \frac{1}{2} \sum_{k} (t_k - y_k)^2 = \frac{1}{2} \sum_{k} \left(t_k - \sum_{i} w_{ik} x_i \right)^2$$

UiO Department of Informatics

Training MLPs

Backward Pass

- Calculate the output errors
- 2. Update last layer of weights.
- 3. Propagate error backward, update hidden weights.
- 4. Until first layer is reached.

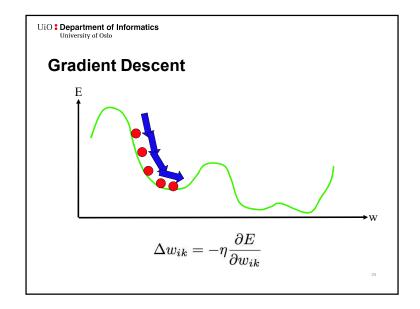

22

UiO Department of Informatics
University of Oslo

Back Propagation Algorithm

- The backpropagation training algorithm uses the *gradient descent* technique to *minimize* the *mean square difference* between the desired and actual outputs.
- The network is trained initially selecting **small random weights** and then presenting all training data incrementally.
- **Weights** are **adjusted** after every trial until they **converge** and the error is reduced to an acceptable value.

Error Terms

- Need to differentiate the error function
- The full calculation is presented in the book.
- Gives us the following error terms (deltas)
 - · For the outputs

$$\delta_k = (y_k - t_k) g'(a_k)$$

• For the hidden nodes

$$\delta_i = g'(u_i) \sum_k \delta_k w_{ik}$$

26

UiO : Department of Informatics
University of Oslo

Update Rules

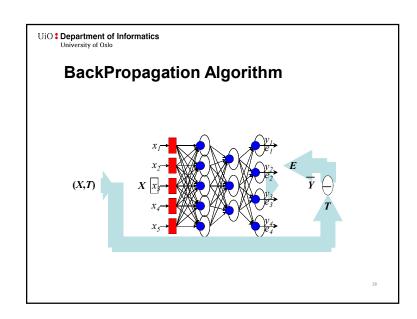

- This gives us the necessary update rules
 - For the weights connected to the outputs:

$$w_{jk} \leftarrow w_{jk} - \eta \delta_k z_j$$

• For the weights on the hidden nodes:

$$v_{ij} \leftarrow v_{ij} - \eta \delta_j x_i$$

• The learning rate η depends on the application. Values between 0.1 and 0.9 have been used in many applications.

UiO : Department of Informatics University of Oslo

Algorithm (sequential)

- 1. Apply an input vector and calculate all activations, a and u
- 2. Evaluate deltas for all output units:

$$\delta_k = (y_k - t_k) g'(a_k)$$

3. Propagate deltas backwards to hidden layer deltas:

$$\delta_i = g'(u_i) \sum_k \delta_k w_{ik}$$

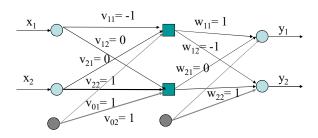

4. Update weights:

$$w_{jk} \leftarrow w_{jk} - \eta \delta_k z_j$$

$$v_{ij} \leftarrow v_{ij} - \eta \delta_j x_i$$

UiO: Department of Informatics

Example: Backpropagation

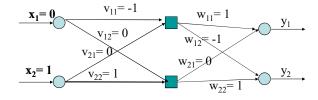

Use identity activation function (ie g(a) = a) for simplicity of example

UiO : Department of Informatics

Example: Backpropagation

All biases set to 1. Will not draw them for clarity.

Learning rate h = 0.1

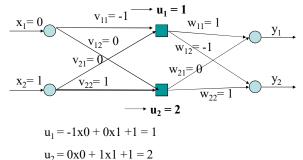

Have input [0 1] with target [1 0].

UiO: Department of Informatics

Example: Backpropagation

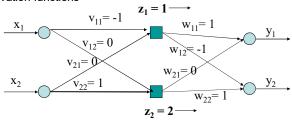

Forward pass. Calculate 1st layer activations:

Olliversity of Oslo

Example: Backpropagation

Calculate first layer outputs by passing activations through activation functions

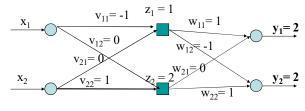

$$z_1 = g(u_1) = 1$$

$$\mathbf{z}_2 = \mathbf{g}(\mathbf{u}_2) = 2$$

 $\mathrm{UiO}\, \mbox{\ensuremath{\stackrel{\bullet}{\circ}}}\, \mbox{\ensuremath{Department}}$ of Informatics

Example: Backpropagation

Calculate 2^{nd} layer outputs (weighted sum through activation functions):

$$y_1 = a_1 = 1x1 + 0x2 + 1 = 2$$

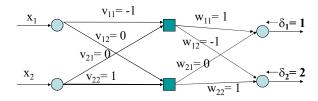

$$y_2 = a_2 = -1x1 + 1x2 + 1 = 2$$

UiO : Department of Informatics
University of Oslo

Example: Backpropagation

Backward pass:

$$\delta_k = (y_k - t_k)g'(a_k)$$

Target =
$$[1, 0]$$
 so $t_1 = 1$ and $t_2 = 0$. So:

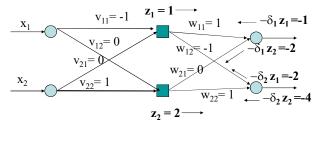

$$\delta_1 = (y_1 - t_1) = 2 - 1 = 1$$

$$\delta_2 = (y_2 - t_2) = 2 - 0 = 2$$

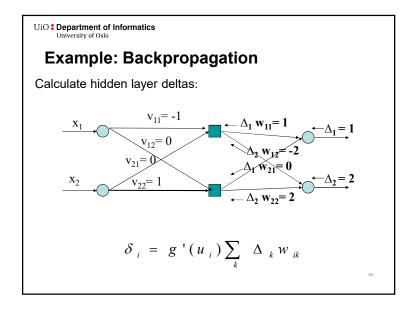

UiO: Department of Informatics

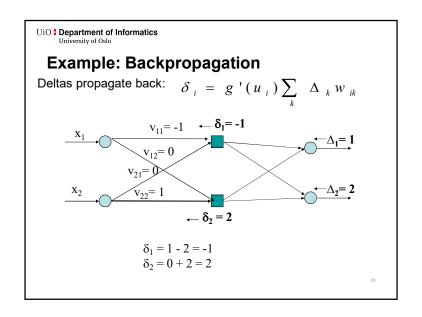

Example: Backpropagation

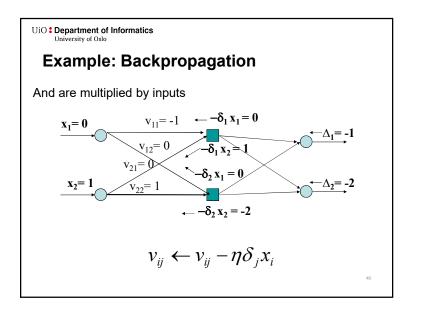

Calculate weight changes for 1st layer:

$$w_{jk} \leftarrow w_{jk} - \eta \delta_k z_j$$

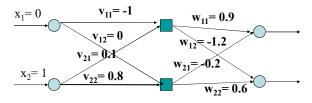

Example: Backpropagation

Finally change weights:

$$v_{ij} \leftarrow v_{ij} - \eta \delta_j x_i$$

Note that the weights multiplied by the zero input are unchanged as they do not contribute to the error

We have also changed biases (not shown)

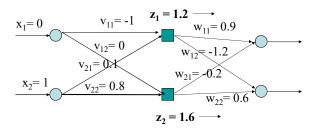

41

UiO : Department of Informatics

University of Oslo

Example: Backpropagation

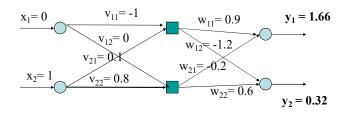

Now go forward again (would normally use a new input vector):

UiO Department of Informatics

Example: Backpropagation

Now go forward again (would normally use a new input vector):

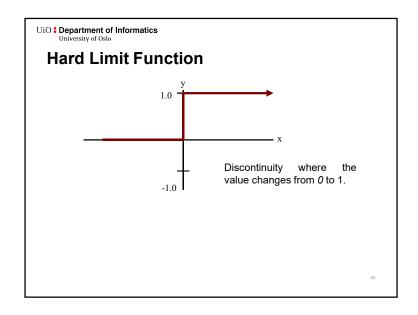

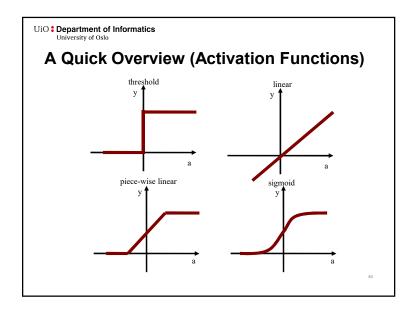

Outputs now closer to target value [1, 0]

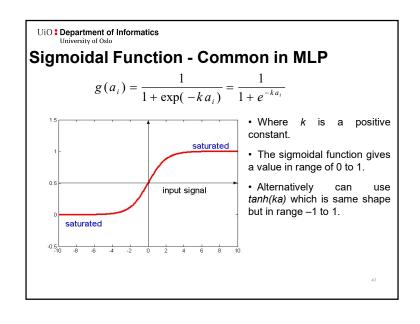

UiO Department of Informatics
University of Oslo

Activation Function

- We need to compute the derivative of activation function \boldsymbol{g}
- What do we want in an activation function?
 - Differentiable
 - · Nonlinear (more powerful)
 - Bounded range (for numerical stability)

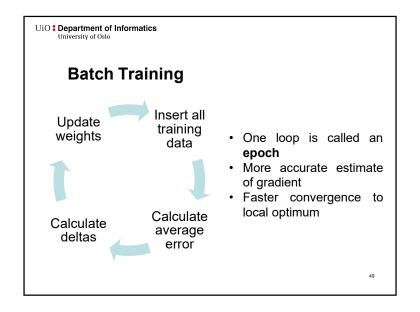

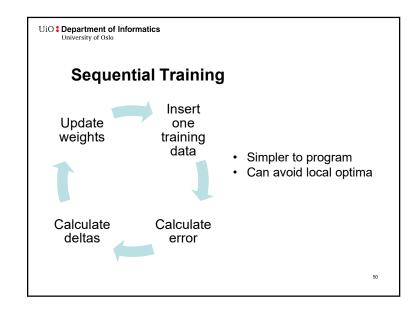

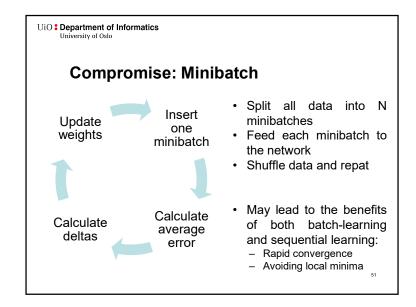

UiO : Department of Informatics
University of Oslo

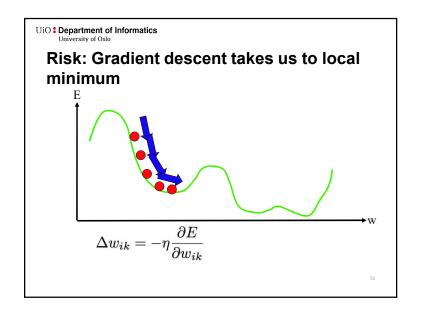

Network Training

- Training set shown repeatedly until stopping criteria are met.
- When should the weights be updated?
 - After all inputs seen (batch)
 - After each input is seen (sequential)
 - Both ways, **need many epochs** passes through the whole dataset

UiO Department of Informatics
University of Oslo

How can we avoid the local minimum?

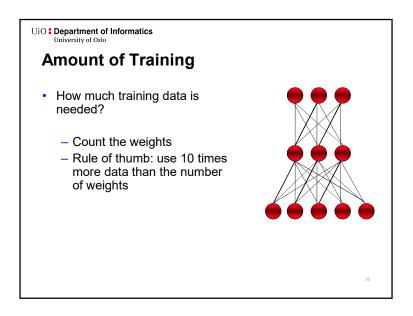

- Initialize training many times with random weights
- Use momentum:

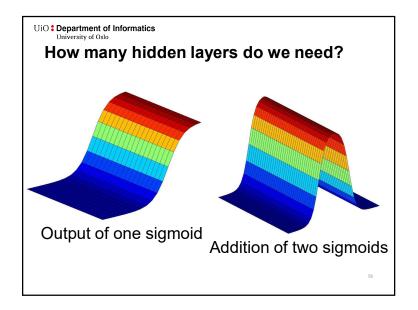

$$w_{ij} \leftarrow w_{ij} - \eta \Delta_j z_i + \alpha \Delta w_{ij}^{t-1}$$

UiO: Department of Informatics
University of Oslo

PRACTICAL ISSUES

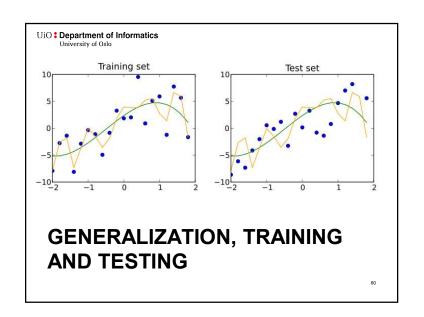

UiO : Department of Informatics
University of Oslo

Network Topology

- How many layers?
- How many neurons per layer?
- No good answers
 - At most 3 weight layers, usually 2
 - · Test several different networks
- Possible types of adaptive algorithms (not default in MLP):
 - start from a large network and successively remove some neurons and links until network performance degrades.
 - begin with a small network and introduce new neurons until performance is satisfactory.

Generalisation

- · Aim of neural network learning:
 - Generalise from training examples to all possible inputs.
- The objective of learning is to achieve good generalization to new cases; we cannot train on all possible data.
- Under-training is bad.
- Over-training is also bad.

61

Given: training images and their categories What are the categories of these test images?

UiO Department of Informatics
University of Oslo

Overfitting

- Overfitting occurs when a model begins to learn the bias
 of the training data rather than learning to generalize.
- Overfitting generally occurs when a model is excessively complex in relation to the amount of data available.
- A model which overfits the training data will generally have poor predictive performance, as it can exaggerate minor fluctuations in the data.

UiO: Department of Informatics

University of Oslo

Overfitting

- The training data contains information about the regularities in the mapping from input to output.
- · Training data also contains bias:
 - There is sampling bias. There will be accidental regularities due to the finite size of the training set.
 - The target values may also be unreliable or noisy.
- When we fit the model, it cannot tell which regularities are relevant and which are caused by sampling error.
 - So it fits both kinds of regularity.
 - If the model is very flexible it can model the sampling error really well. This is not what we want.

65

UiO Department of Informatics

The Solution: Cross-Validation

To maximize generalization and avoid overfitting, split data into three sets:

- Training set: Train the model.
- Validation set: Judge the model's generalization ability during training.
- Test set: Judge the model's generalization ability after training.

The Problem of Overfitting

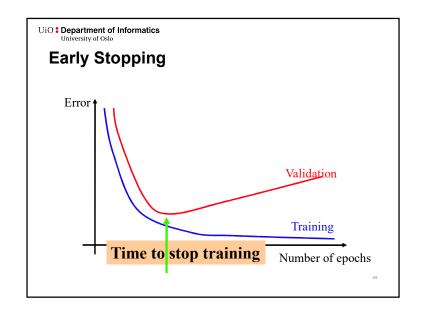

• Approximation of the function y = f(x):

2 neurons in hidden layer
5 neurons in hidden layer
40 neurons in hidden layer

UiO Department of Informatics
University of Oslo

Validation set

- Data unseen by training algorithm not used for backpropagation.
- Network is not trained on this data, so we can use it to measure generalization ability.
- Goal is to maximize generalization ability, so we should minimize the error on this data set.

Testing set

Data unseen during training and validation.
Has no influence on when to stop training.
With early stopping, we've maximized the ability to generalize to the validation set;
To judge the final result, we should measure its ability to generalize to completely unseen data.
