- Demo

# Complexity of a Chess Game

- **20** possible start moves, **20** possible replies, etc.
- **400** possible positions after **2** ply (half moves)
- **197 281** positions after **4** ply
- $7^{13}$  positions after 10 ply (5 White moves and 5 Black moves)
- **Exponential explosion!**
- Approximately **40 legal moves** in a typical position
- There exists about  **$10^{120}$**  possible chess games

# Solving Chess, is it a myth?

## Chess Complexity Space

- The estimated number of possible chess games is  $10^{120}$ 
  - Claude E. Shannon
  - 1 followed by 120 zeroes!!!
- The estimated number of reachable chess positions is  $10^{47}$ 
  - Shirish Chinchalkar, 1996
- Modern GPU's performs  $10^{13}$  flops
- If we assume one million GPUs with 10 flops per position we can calculate  $10^{18}$  positions per second
- It will take us 1 600 000 000 000 000 000 years to solve chess

## Assuming Moore's law works in the future

- Today's top supercomputers delivers  $10^{16}$  flops
- Assuming 100 operations per position yields  $10^{14}$  positions per second
- Doing retrograde analysis on supercomputers for 4 months we can calculate  $10^{21}$  positions.
- When will Moore's law allow us to reach  $10^{47}$  positions?
- Answer: in 128 years, or around year 2142!

# History of Computer Chess

- Chess is a good fit for computers:
  - **Clearly defined rules**
  - Game of **complete information**
  - **Easy to evaluate (judge) positions**
  - **Search tree is not too small or too big**
- 1950: Programming a Computer for Playing Chess (Claude Shannon)
- 1951: First chess playing program (on paper) (Alan Turing)
- 1958: First computer program that can play a complete chess game
- 1981: Cray Blitz wins a tournament in Mississippi and achieves master rating
- 1989: Deep Thought loses 0-2 against World Champion Garry Kasparov
- 1996: Deep Blue wins a game against Kasparov, but loses match 2-4
- 1997: Upgraded Dee Blue wins 3.5-2.5 against Kasparov
- 2005: Hydra destroys GM Michael Adams 5.5-0.5
- 2006: World Champion Vladimir Kramnik loses 2-4 against Deep Fritz (PC chess engine)

# Search Trees and Position Evaluation

- Search trees (nodes are positions, edges are legal chess moves)
- Leaf nodes are end positions which needs to be evaluated (judged)
- A simple judger: Check mate? If not, count material
- Nodes are marked with a numeric evaluation value

# Minimax: The Basic Search Algorithm

- Minimax: Assume that both White and Black plays the best moves. We maximizes White's score
- Perform a **depth-first search** and **evaluate** the **leaf nodes**
- Choose child node with **highest value** if it is **White** to move
- Choose child node with **lowest value** if it is **Black** to move
- **Branching factor** is **40** in a typical chess position

 ply = 2  
 ply = 3  
 ply = 4

# NegaMax – “Simplified” Minimax

## Minimax

```
int maxi( int depth ) {
    if ( depth == 0 )
        return evaluate();
    int max = -oo;
    for ( all moves ) {
        score = mini( depth - 1 );
        if( score > max )
            max = score;
    }
    return max;
}
```

```
int mini( int depth ) {
    if ( depth == 0 )
        return -evaluate();
    int min = +oo;
    for ( all moves ) {
        score = maxi( depth - 1 );
        if( score < min )
            min = score;
    }
    return min;
}
```

## NegaMax

$\text{max}(a, b) == -\text{min}(-a, -b)$

```
int negaMax( int depth ) {
    if ( depth == 0 ) return evaluate();
    int max = -oo;
    for ( all moves ) {
        score = -negaMax( depth - 1 );
        if( score > max )
            max = score;
    }
    return max;
}
```

# Node explosion

A typical middle-game position has 40 legal moves.

Depth	Node count	Time at 10M nodes / s
1	40	0.000004 s
2	1 600	0.00016 s
3	64 000	0.0064 s
4	2 560 000	0.256 s
5	102 400 000	10.24 s
6	4 096 000 000	6 min 49,6 s
7	163 840 000 000	4 h 33 min 4 s
8	6 553 600 000 000	7 d 14 h 2 min 40 s

- 10 M nodes per second (nps) is realistic for modern chess engines
- Modern engines routinely reach depths 20-25 ply at tournament play
- But they only have a few minutes per move, so they should be able to go only 5-6 ply deep
- How do they then get to depth 20 so easily?

# Pruning Techniques

- The complexity of searching  $d$  ply ahead is  $O(b * b * \dots * b) = O(b^d)$
- With a branching factor ( $b$ ) of 40 it is crucial to be able to prune the search tree

# Alpha-Beta Pruning

**“Position is so good for White (or Black) that the opponent with best play will not enter the variation that gives the position.”**

- Use previous known max and min values to limit the search tree
- Alpha value: White is guaranteed this score or better (start value:  $-\infty$ )
- Beta value: Black is guaranteed this score or less (start value:  $+\infty$ )
- If Alpha is higher than Beta, then the position will never occur assuming best play
- If search tree below is evaluated left to right, then we can skip the greyed-out sub trees
- Regardless of what values we get for the grey nodes, they will not influence the root node score

ply = 0  
ply = 1  
ply = 2  
ply = 3  
ply = 4

# Analyze the Best Move First

- Even with alpha-beta pruning, if we always start with the worst move, we still get  $O(b * b * .. * b) = O(b^d)$
- If we always start with the best move (also recursive) it can be shown that complexity is  $O(b * 1 * b * 1 * b * 1 ..) = O(b^{d/2}) = O(\sqrt{b^d})$
- We can **double** the **search depth** without using more resources
- Conclusion: It is very important to try to **start** with the **strongest moves first**

# Killer-Move Heuristics

- Killer-move heuristics is based on the assumption that a **strong move** which gave a **large pruning** of a sub tree, might also be a strong move in **other nodes** in the search tree
- Therefore we start with the killer moves in order to maximize search tree pruning

# Zero-Move Heuristics

- Alpha-Beta cutoff: “The position is so good for White (or Black) that the opponent with best play will avoid the variation resulting in that position”
- Zero-Move heuristics is based on the fact that in most positions it is an **advantage** to be the **first player to move**
- Let the player (e.g. White) who has just made a move, play another move (**two moves in a row**), and perform a shallower (2-3 ply less) and therefore cheaper search from that position
- If the shallower search gives a cutoff value (e.g. bad score for White), it means that most likely the search tree can be **pruned** at this position without performing a deeper search, since **two moves in a row did not help**
- Very effective pruning technique!
- Cavecats: Check and endgames (where a player can be in “trekktvang” – every move worsens the position)

# Iterative Deeper Depth-First Search (IDDFS)

- Since it is so important to evaluate the best move first, it might be worthwhile to execute a **shallower search** first and then use the resulting **alpha/beta cutoff values** as **start values** for a **deeper search**
- Since the **majority** of search **nodes** are on the **lowest level** in a balanced search tree, it is relatively cheap to do an extra shallower search

# Search Tree Extensions

- PC programs today can compute **18-22 ply ahead** (Deep Blue computed 12 ply against Kasparov in 1997, Hydra (64 nodes with FPGAs) computed at least 18 ply)
- It is important to **extend** the search in leaf nodes that are “**unstable**”
- Good **search extensions** includes all moves that gives **check** or **captures** a piece
- The longest search extensions are typically **double** the average length of the search tree!

# Transposition Table

- **Same position** will commonly occur from **different move orders**
- All chess engines therefore has a **transposition table** (position cache)
- Implemented using a **hash table** with chess position as key
- Doesn't have to evaluate large sub trees over and over again
- Chess engines typically uses half of available memory to hash table – proves how important it is

# Other challenges

- Move generator (hardware / software)
  - Hydra (64 nodes Xeon cluster, FPGA chips) computed 200 millions positions per second, approximately the same as Deep Blue (on older ASIC chip sets)
  - Hydra computes 18 ply ahead while Deep Blue only managed 12 (Hydra prunes search tree better)
  - Fritz 13 chess engine (single processor/core) manages 2.3 mill moves/second on my laptop and computes 15+ ply
  - Efficient data structure for a chess board (0x88, bitboards)
  - Opening library suited for a chess computer
  - Position evaluation:
    - Traditionally chess computers has done **deep searches** with a **simple evaluation function**
    - But one of the best PC chess engines today, Rybka, sacrifices search depth for a **complex position evaluation** and better search heuristics

# Endgame Tablebases

- Chess engines plays endgames with 3-7 pieces left on the board perfectly by **looking up best move in huge tables**
- These endgame databases are called **Tablebases**
- Retrograde analyses: Tablebases are generated by starting with **final positions** (check mate, steal mate or insufficient mating material (e.g. king vs. king)) and then **compute backwards** until all nodes in search tree are marked as win, draw or loose
- Using complex **compression** algorithms (Eugene Nalimov)
- All 3-5 piece endgames and some 6 piece endgames are stored in just 21 GB
- [http://en.wikipedia.org/wiki/Nalimov\\_tablebase](http://en.wikipedia.org/wiki/Nalimov_tablebase)

# Lomonosov Tablebases

- All 7 piece endgames (except 6 pieces vs a lone king) calculated for the first time in 2013 on the Lomonosov supercomputer in Moscow State University.
- Took 6 months to generate
- Needed 140 TB of storage
- Longest forced mate:  
White to mate in 545 moves!

- See [http://chessok.com/?page\\_id=27966](http://chessok.com/?page_id=27966)

# Demo

- Demo: ChessBase with chess engine Deep Rybka 4, Houdini 4, Komodo 8 and Fritz 13
- Best open source UCI chess engine (and may be best overall):
  - Stockfish ([stockfishchess.org](http://stockfishchess.org))
