Intro

INF4140 - Models of concurrency Intro, lecture 1

Høsten 2014

29. 08. 2014

Today's agenda

Introduction

- overview
- motivation
- simple examples and considerations

Start

- a bit about
 - concurrent programming with critical sections and waiting.
 Read^a also [Andrews, 2000, chapter 1] for some background
 - interference
 - the await-language

^ayou!, as course particpant

What this course is about

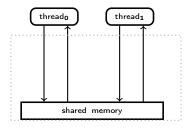

- Fundamental issues related to cooperating parallel processes
- How to think about developing parallel processes
- Various language mechanisms, design patterns, and paradigms
- Deeper understanding of parallel processes:
 - (informal and somewhat formal) analysis
 - properties

Parallel processes

- Sequential program: one control flow thread
- Parallel program: several control flow threads

Parallel processes need to exchange information. We will study two different ways to organize communication between processes:

- Reading from and writing to shared variables (part I of the course)
- Communication with messages between processes (part II of the course)

Course overview – part I: Shared variables

- atomic operations
- interference
- deadlock, livelock, liveness, fairness
- parallel programs with locks, critical sections and (active) waiting
- semaphores and passive waiting
- monitors
- formal analysis (Hoare logic), invariants
- Java: threads and synchronization

Course overview – part II: Communication

- asynchronous and synchronous message passing
- basic mechanisms: RPC (remote procedure call), rendezvous, client/server setting, channels
- Java's mechanisms
- analysis using histories
- asynchronous systems

Part I: shared variables

Why shared (global) variables?

- reflected in the HW in conventional architectures
- there may be several CPUs inside one machine (or multi-core nowadays).
- natural interaction for tightly coupled systems
- used in many important languages, e.g., Java's multithreading model.
- even on a single processor: use many processes, in order to get a natural partitioning
- potentially greater efficiency and/or better latency if several things happen/appear to happen "at the same time".

e.g.: several active windows at the same time

 $^{^{1}}$ Holds for concurrency in general, not just shared vars, of course. $\leftarrow \ge$

Simple example

Global variables: x, y, and z. Consider the following program:

$$x := x + z; y := y + z;$$

Pre/post-condition

- executing a program (resp. a program fragment) ⇒ state-change
- the conditions describe the state of the global variables before and after a program statement
- These conditions are meant to give an understanding of the program, and are not part of the executed code.

Can we use parallelism here (without changing the results)?

If operations can be performed *independently* of one another, then concurrency may increase performance

Simple example

Global variables: x, y, and z. Consider the following program:

```
before \{ x \text{ is a and } y \text{ is } b \} x := x + z; y := y + z;
```

Pre/post-condition

- executing a program (resp. a program fragment) ⇒ state-change
- the conditions describe the state of the global variables before and after a program statement
- These conditions are meant to give an understanding of the program, and are not part of the executed code.

Can we use parallelism here (without changing the results)?

If operations can be performed *independently* of one another, then concurrency may increase performance

Simple example

Global variables: x, y, and z. Consider the following program:

```
before \{ \ x \ \text{is a and } y \ \text{is } b \ \} \quad x := x+z; y := y+z; \quad \{ \ x \ \text{is } a+z \ \text{and } y \ \text{is } b+z \ \}
```

Pre/post-condition

- executing a program (resp. a program fragment) ⇒ state-change
- the conditions describe the state of the global variables before and after a program statement
- These conditions are meant to give an understanding of the program, and are not part of the executed code.

Can we use parallelism here (without changing the results)?

If operations can be performed *independently* of one another, then concurrency may increase performance

Parallel operator |

Extend the language with a construction for parallel composition:

co
$$S_1 \parallel S_2 \parallel \ldots \parallel S_n$$
 oc

Execution of a parallel composition happens via the concurrent execution of the component processes S_1, \ldots, S_n and terminates normally if all component processes terminate normally.

Example

$$\{ x \text{ is } a, y \text{ is } b \} x := x + z ; y := y + z \{ x = a + z, y = b + z \}$$

Parallel operator |

Extend the language with a construction for parallel composition:

co
$$S_1 \parallel S_2 \parallel \ldots \parallel S_n$$
 oc

Execution of a parallel composition happens via the concurrent execution of the component processes S_1, \ldots, S_n and terminates normally if all component processes terminate normally.

Example

$$\{ x \text{ is } a, y \text{ is } b \} \text{ } \mathbf{co} x := x + z \parallel y := y + z \text{ } \mathbf{oc} \{ x = a + z, y = b + z \}$$

Interaction between processes

Processes can interact with each other in two different ways:

- cooperation to obtain a result
- competition for common resources

The organization of this interaction is what we will call *synchronization*.

Synchronization

Synchronization (veeeery abstractly) = restricting the possible interleavings of parallel processes (so as to avoid "bad" things to happen and to achieve "positive" things)

- increasing "atomicity" and mutual exclusion (Mutex): We introduce critical sections of which cannot be executed concurrently
- Condition synchronization: A process must wait for a specific condition to be satisfied before execution can continue.

Concurrent processes: Atomic operations

Definition (Atomic)

An operation is atomic if it cannot be subdivided into smaller components.

Note

- A statement with at most one atomic operation, in addition to operations on local variables, can be considered atomic!
- We can do as if atomic operations do not happen concurrently!
- What is atomic depends on the language/setting: fine-grained and coarse-grained atomicity.
- e.g.: Reading and writing of a global variable is usually atomic.²
- For some (high-level) languages: assignments x := e atomic operations, for others, not (reading of the variables in the expression e, computation of the value e, followed by writing to x.)

Atomic operations on global variables

- fundamental for (shared var) concurrency
- also: process communication may be represented by variables: a communication channel corresponds to a variable of type vector.
- associated to global variables: a set of atomic operations
- typically: read + write,
- in HW, e.g. LOAD/STORE
- channels as gobal data: send and receive
- x-operations: atomic operations on a variable x

Mutual exclusion

Atomic operations on a variable cannot happen simultaneously.

Example

$$P_1$$
 P_2 { $x = 0$ } $\cos x := x + 1 \parallel x := x - 1 \text{ oc}$ { ? }

final state? (i.e., post-condition)

- Assume:
 - each process is executed on its own processor
 - and/or: the processes run on a multi-tasking OS

and that x is part of a shared state space, i.e. a shared var

- Arithmetic operations in the two processes can be executed simultaneously, but read and write operations on x must be performed sequentially/atomically.
- order of these operations: dependent on relative processor speed and/or scheduling
- outcome of such programs: difficult to predict!
- "race" on x or race condition
- as for races in practice: it's simple, avoid them at (almost) all costs

Atomic read and write operations

$$\{ x = 0 \} \quad \cos x := x + 1 \parallel x := x - 1 \text{ oc } \{ ? \}$$

Listing 1: Atomic steps for x := x + 1

```
read x;
inc;
write x;
```

4 atomic x-operations:

- P_1 reads (R1) value of x
- P_1 writes (W1) a value into x,
- P_2 reads (R2) value of x, and
- P_2 writes (W2) a value into x.

Interleaving & possible execution sequences

- "program order":3
 - R1 must happen before W1 and
 - R2 before W2
- inc and dec ("-1") work process-local⁴
- ⇒ remember (e.g.) inc; write x behaves "as if" atomic (alternatively read x; inc)

operations can be sequenced in 6 ways ("interleaving")

R1	R1	R1	R2	R2	R2
W1	R2	R2	R1	R1	W2
R2	W1	W2	W1	W2	R1
W2	W2	W1	W2	W1	W1
0	-1	1	-1	1	0

³A word aside: as natural as this seems: in a number of modern architecture/modern languages & their compilers, this is not guaranteed! Cf. Java's memory model, or weak memory models in general.

⁴e.g.: in an arithmetic register, or a local variable (not mentioned in the code).

Non-determinism

- final states of the program (in x): $\{0, 1, -1\}$
- Non-determinism: result can vary depending on factors *outside* the program code
 - timing of the execution
 - scheduler
- as (post)-condition: $x = -1 \lor x = 0 \lor x = 1$

 $^{^5}$ Of course, things like $x \in \{-1,0,1\}$ or $-1 \le x \le 1$ are equally adequate formulations of the postcondition.

Non-determinism

- final states of the program (in x): $\{0, 1, -1\}$
- Non-determinism: result can vary depending on factors *outside* the program code
 - timing of the execution
 - scheduler
- as (post)-condition: $x = -1 \lor x = 0 \lor x = 1$

$$\{ \ \} \ x := 0; co x := x + 1 \parallel x := x - 1 oc; \ \{ x = -1 \lor x = 0 \lor x = 1 \ \}$$

 $^{^5}$ Of course, things like $x \in \{-1,0,1\}$ or $-1 \le x \le 1$ are equally adequate formulations of the postcondition.

State-space explosion

- Assume 3 processes, each with the same number of atomic operations
- consider executions of $P_1 \parallel P_2 \parallel P_3$

nr. of atomic op's	nr. of executions
2	90
3	1680
4	34 650
5	756 756

- different executions can lead to different final states.
- even for simple systems: impossible to consider every possible execution

For n processes with m atomic statements each:

number of exec's =
$$\frac{(n * m)!}{m!^n}$$

The "at-most-once" property

Fine grained atomicity

only the very most basic operations (R/W) are atomic "by nature"

- however: some non-atomic interactions appear to be atomic.
- note: expressions do only read-access (≠ statements)
- critical reference (in an e): a variable changed by another process
- e without critical reference \Rightarrow evaluation of e as if atomic

Definition (At-most-once property)

x := e satisfies the "amo"-property if

- 1. e contains no crit. reference
- 2. e with at most one crit. reference & x not referenced^a by other proc's

^aor just read

The "at-most-once" property

Fine grained atomicity

only the very most basic operations (R/W) are atomic "by nature"

- however: some non-atomic interactions appear to be atomic.
- note: expressions do only read-access (≠ statements)
- critical reference (in an e): a variable changed by another process
- e without critical reference \Rightarrow evaluation of e as if atomic

Definition (At-most-once property)

x := e satisfies the "amo"-property if

- 1. e contains no crit. reference
- 2. e with at most one crit. reference & x not referenced by other proc's

^aor just read.

At most once examples

- In all examples: initially x = y = 0. And r, r' etc: local var's (registers)
- ullet co and oc around ... $\| \dots$ omitted

```
\begin{array}{l} x := x + 1 \parallel y := x + 1 \\ x := y + 1 \parallel y := x + 1 \qquad \{ \ (x,y) \in \{(1,1),(1,2),(2,1)\} \ \} \\ x := y + 1 \parallel x := y + 3 \parallel y := 1 \qquad \{ y = 1 \land x = 1,2,3,4\} \\ r := y + 1 \parallel r' := y - 1 \parallel y := 5 \\ r := x - x \parallel \dots \qquad \{ \text{is r now 0?} \} \\ x := x \parallel \dots \qquad \{ \text{same as skip?} \} \\ \text{if } y > 0 \text{ then } y := y - 1 \text{ fi} \parallel \text{if } y > 0 \text{ then } y := y - 1 \text{ fi} \\ \end{array}
```

The course's first programming language: the await-language

- the usual sequential, imperative constructions such as assignment, if-, for- and while-statements
- cobegin-construction for parallel activity
- processes
- critical sections
- await-statements for (active) waiting and conditional critical sections

Syntax

We use the following syntax for non-parallel control-flow⁶

```
Declarations
                          Assignments
int i = 3:
                          x := e:
int a[1:n];
                          a[i] := e;
int a[n]:7
                          a[n]++:
int a[1:n] = ([n] 1):
                          sum +:= i;
Seq. composition
                          statement: statement
Compound statement
                          {statements}
Conditional
                          if statement
While-loop
                          while (condition) statement
                          for [i = 0 \text{ to } n-1] statement
For-loop
```

⁶The book uses more C/Java kind of conventions, like = for assignment and == for logical equality.

⁷corresponds to: int a[0:n-1]

Parallel statements

$$co S_1 \parallel S_2 \parallel \ldots \parallel S_n oc$$

- The statement(s) of each arm S_i are executed in parallel with thos of the other arms.
- Termination: when all "arms" S_i have terminated ("join" synchronization)

Parallel processes

```
process foo {
   int sum := 0;
   for [i=1 to 10]
      sum +:= 1;
      x := sum;
}
```

- Processes evaluated in arbitrary order.
- Processes are declared (as methods/functions)
- side remark: the convention "declaration = start process" is not used in practice.⁸

⁸one typically separates declaration/definition from "activation" (with good reasons). Note: even *instantiation* of a runnable interface in Java starts a process. Initialization (filling in initial data into a process) is tricky business.

```
process bar1 dir0o
for [i = 1 to n]
write(i); }
```

```
process bar2[i=1 to n] dir0o
write(i);
}
```

Starts one process.

The numbers are printed in increasing order.

Starts *n* processes.

The numbers are printed in arbitrary order because the execution order of the process is *non-deterministic*.

Read- and write-variables

- V : statement → variable set: set of global variables in a statement (also for expressions)
- W: statement \rightarrow variable set set of global write-variables

$$\mathcal{V}(x := e) = \mathcal{V}(e) \cup \{x\}$$
 $\mathcal{V}(S_1; S_2) = \mathcal{V}(S_1) \cup \mathcal{V}(S_2)$
 $\mathcal{V}(\text{if } b \text{ then } S) = \mathcal{V}(b) \cup \mathcal{V}(S)$
 $\mathcal{V}(\text{while } (b)S) = \mathcal{V}(b) \cup \mathcal{V}(S)$

 ${\cal W}$ analogously, except the most important difference:

$$\mathcal{W}(x := e) = \{x\}$$

note: expressions side-effect free

Disjoint processes

 Parallel processes without common (=shared) global variables: without interference

$$\mathcal{V}(S_1)\cap\mathcal{V}(S_2)=\emptyset$$

- read-only variables: no interference.
- The following *interference criterion* is thus sufficient:

$$\mathcal{V}(S_1) \cap \mathcal{W}(S_2) = \mathcal{W}(S_1) \cap \mathcal{V}(S_2) = \emptyset$$

- cf. notion of race (or race condition)
- remember also: critical references/amo-property
- programming practice: final variables in Java

Semantic concepts

- A *state* in a parallel program consists of the values of the global variables at a given moment in the execution.
- Each process executes independently of the others by *modifying* global variables using atomic operations.
- An execution of a parallel program can be modelled using a history, i.e. a sequence of operations on global variables, or as a sequence of states.
- For non-trivial parallel programs: very many possible histories.
- synchronization: conceptually used to *limit* the possible histories/interleavings.

Properties

- property = predicate over programs, resp. their histories
- A (true) *property* of a program⁹ is a predicate which is true for all possible histories of the program.
- Two types:
 - safety property: program will not reach an undesirable state
 - liveness property: program will reach a desirable state.
- partial correctness: If the program terminates, it is in a desired final state (safety property).
- termination: all histories are finite. 10
- total correctness: The program terminates and is partially correct.

⁹the program "has" that property, the program satisfies the property . . .

¹⁰that's also called *strong* termination. Remember: non-determinism.

Properties: Invariants

- invariant (adj): constant, unchanging
- cf. also "loop invariant"

Definition (Invariant)

an invariant = state property, which holds for holds for all reachable states.

- safety property
- appropriate for also non-terminating systems (does not talk about a final state)
- global invariant talks about the state of many processes at once, preferably the entire system
- local invariant talks about the state of one process

proof principle: induction

one can show that an invariant is correct by

- 1. showing that it holds initially,
- 2. and that each atomic statement maintains it.

How to check properties of programs?

- Testing or debugging increases confidence in a program, but gives no guarantee of correctness.
- Operational reasoning considers all histories of a program.
- Formal analysis: Method for reasoning about the properties of a program without considering the histories one by one.

Dijkstra's dictum:

A test can only show errors, but "never" prove correctness!

Critical sections

Mutual exclusion: combines sequences of operations in a *critical* section which then behave like atomic operations.

- When the non-interference requirement parallel processes does not hold, we use synchronization to restrict the possible histories.
- Synchronization gives coarse-grained atomic operations.
- The notation $\langle S \rangle$ means that S is performed atomically.¹¹

Atomic operations:

- Internal states are *not visible* to other processes.
- Variables cannot be changed underway by other processes.
- S: like executed in a transaction

Example The example from before can now be written as:

int
$$x := 0$$
; co $\langle x := x + 1 \rangle \| \langle x := x - 1 \rangle$ oc $\{ x = 0 \}$

 $^{^{11} {\}rm In}$ programming languages, one could find it as ${\tt atomic} \{ \! \! \mathcal{S} \}$ or similar.

Conditional critical sections

Await statement

$$\langle await(b) S \rangle$$

- boolean condition b: await condition
- body S: executed atomically (conditionally on b)

Example

$$\langle await(y > 0) \ y := y - 1 \rangle$$

• synchronization: decrement delayed until (if ever) y > 0 holds

2 special cases

unconditional critical section or "mutex"

$$\langle x := 1; y := y + 1 \rangle$$

Condition synchronization:¹³

$$\langle await(counter > 0) \rangle$$

¹²Later, a special kind of semaphore (a binary one) is also called a "mutex". Terminology is a bit flexible sometimes.

¹³one may also see sometimes just await(b): however, eval. of b better be atomic and under no circumstances must b have side-effects (never, ever. Seriously).

Typical pattern

```
int counter = 1;

await (counter > 0)

counter := counter -1; > // start CS

critical statements;
counter := counter+1 // end CS
```

- "critical statements" *not* enclosed in \(\text{angle brackets} \). Why?
- invariant: $0 \le counter \le 1$ (= counter acts as "binary lock")
- very bad style would be: touch counter inside "critical statements" or elsewhere (e.g. access it not following the "await-inc-CR-dec" pattern)
- in practice: beware(!) of exceptions in the critical statements

Example: (rather silly version of) producer/consumer synchronization

- strong coupling
- buf as shared variable ("one element buffer")
- synchronization
 - coordinating the "speed" of the two procs (rather strictly here)
 - to avoid, reading data which is not yet produced
 - (related:) avoid w/r conflict on shared memory

```
int buf, p := 0; c := 0;
2
3
   process Producer {
                                       process Consumer {
     int a[N];...
                                       int b[N];...
5
     while (p < N) {
                                       while (c < N) {
6
       < await (p = c); >
                                        < await (p > c); >
7
       buf := a[p];
                                         b[c] := buf;
8
          p := p+1;
                                            c := c+1:
10
11
```

Example (continued)

a ·		l	l .
a .		l	l .
		l	l .

ouf:	p:	c:	n:	_
------	----	----	----	---

- An invariant holds in all states in all histories (traces/executions) of the program (starting in its initial state(s)).
- Global invariant: $c \le p \le c+1$
- Local invariant (Producer): $0 \le p \le n$

Locks & barriers

INF4140 - Models of concurrency

Locks & barriers, lecture 2

Høsten 2014

5. 9. 2014

Practical Stuff

Mandatory assignment 1 ("oblig")

- Deadline: Friday September 26 at 18.00
- Possible to work in pairs
- Online delivery (Devilry): https://devilry.ifi.uio.no

Introduction

- Central to the course are general mechanisms and issues related to parallel programs
- Previous class: await language and a simple version of the producer/consumer example

Today

- Entry- and exit protocols to *critical sections*
 - Protect reading and writing to shared variables
- Barriers
 - Iterative algorithms:

 Processes must *synchronize* between each iteration
 - Coordination using flags

Introduction

- Central to the course are general mechanisms and issues related to parallel programs
- Previous class: await language and a simple version of the producer/consumer example

Today

- Entry- and exit protocols to critical sections
 - Protect reading and writing to shared variables
- Barriers
 - Iterative algorithms:

 Processes must *synchronize* between each iteration
 - Coordination using flags

```
int buf, p := 0; c := 0;

process Producer {
    int a[N];...
    while (p < N) {
        < await (p = c); >
        buf := a[p];
        p := p+1;
    }
}

int b[N];...
while (c < N) {
        < await (p > c); >
        b[c] := buf;
        c := c+1;
}
}
```

Invariants

2

3

5

6 7

8

10 11

- global invariant:
- local (in the producer):

```
int buf, p := 0; c := 0;
2
3
   process Producer {
                                       process Consumer {
     int a[N];...
5
                                       int b[N];...
     while (p < N) {
                                       while (c < N) {
7
       < await (p = c); >
                                        < await (p > c); >
        buf := a[p];
                                         b[c] := buf;
8
          p := p+1;
                                            c := c+1;
10
11
```

Invariants

- global invariant:
- local (in the producer):

Critical section

- Fundamental for concurrency
- Immensely intensively researched, many solutions
- Critical section: part of a program that is/needs to be "protected" against interference by other processes
- Execution under mutual exclusion
- Related to "atomicity"

Main question we are discussing today:

How can we implement critical sections / conditional critical sections?

- Various solutions and properties/guarantees
- Using locks and low-level operations
- SW-only solutions? HW or OS support?
- Active waiting (later semaphores and passive waiting)

How can we implement critical sections / conditional critical sections?

- Various solutions and properties/guarantees
- Using locks and low-level operations
- SW-only solutions? HW or OS support?
- Active waiting (later semaphores and passive waiting)

Access to Critical Section (CS)

- Several processes compete for access to a shared resource
- Only one process can have access at a time: "mutual exclusion" (mutex)
- Possible examples:
 - Execution of bank transactions
 - Access to a printer
- A solution to the CS problem can be used to implement await-statements

Access to Critical Section (CS)

- Possible examples:
 - Execution of bank transactions
 - Access to a printer
- A solution to the CS problem can be used to implement await-statements

Critical section: First approach to a solution

Operations on shared variables happen inside the CS. Access to the CS must then be protected to prevent interference.

```
process p[i=1 to n] {
    while (true) {
        CSentry # entry protocol to CS
        CS
        CSexit # exit protocol from CS
        non-CS
    }
}
```

General pattern for CS

- Assumption: A process which enters the CS will eventually leave it.
- ⇒ Programming advice: be aware of exceptions inside CS!

Critical section: First approach to a solution

Operations on shared variables happen inside the CS. Access to the CS must then be protected to prevent interference.

General pattern for CS

General pattern for CS

- Assumption: A process which enters the CS will eventually leave it.
- ⇒ Programming advice: be aware of exceptions inside CS!

Naive solution

```
int in = 1
                                # possible values in {1,2}
1
2
3
     process p1 {
4
5
                                    process p2 {
        while (true) {
                                      while (true) {
6
          while (in=2) \{skip\};
                                        while (in=1) {skip};
7
          CS:
                                        CS:
8
          in := 2;
                                        in := 1
          non-CS
                                        non-CS
10
```

- entry protocol: active/busy waiting
- exit protocol: atomic assignment

```
int in = 1
                                # possible values in {1,2}
2
3
4
5
     process p1 {
                                   process p2 {
        while (true) {
                                    while (true) {
6
          while (in=2) {skip};
                                        while (in=1) {skip};
7
8
          CS:
                                        CS:
         in := 2;
                                        in := 1
          non-CS
                                        non-CS
10
```

- entry protocol: active/busy waiting
- exit protocol: atomic assignment

Good solution? A solution at all? What's good, what's less so?

```
int in = 1
                                # possible values in {1,2}
2
3
      process p1 {
                                   process p2 {
        while (true) {
                                      while (true) {
5
          while (in=2) {skip};
                                        while (in=1) {skip};
6
          CS:
                                        CS:
8
          in := 2;
                                        in := 1
          non-CS
                                        non-CS
10
```

- entry protocol: active/busy waiting
- exit protocol: atomic assignment

Good solution? A solution at all? What's good, what's less so?

- More than 2 processes?
- Different execution times?

Desired properties

- Mutual exclusion (Mutex): At any time, at most one process is inside CS.
- 2. Absence of deadlock: If all processes are trying to enter CS, at least one will succeed.
- Absence of unnecessary delay: If some processes are trying to enter CS, while the other processes are in their non-critical sections, at least one will succeed.
- Eventual entry: A process attempting to enter CS will eventually succeed.

NB: The three first are safety properties, ¹⁴ The last a liveness property.

(SAFETY: no bad state, LIVENESS: something good will happen.)

Desired properties

NB: The three first are safety properties, ¹⁴ The last a liveness property.

(SAFETY: no bad state, LIVENESS: something good will happen.)

 $^{^{14}}$ The question for points 2 and 3, whether it's safety or liveness, is slightly up-to discussion/standpoint!

Safety: Invariants (review)

A safety property expresses that a program does not reach a "bad" state. In order to prove this, we can show that the program will never leave a "good" state:

- Show that the property holds in all initial states
- Show that the program statements preserve the property

Such a (good) property is often called a global invariant.

Safety: Invariants (review)

A safety property expresses that a program does not reach a "bad" state. In order to prove this, we can show that the program will never leave a "good" state:

- Show that the property holds in all initial states
- Show that the program statements preserve the property

Such a (good) property is often called a global invariant.

Safety: Invariants (review)

A safety property expresses that a program does not reach a "bad" state. In order to prove this, we can show that the program will never leave a "good" state:

- Show that the property holds in all initial states
- Show that the program statements preserve the property

Such a (good) property is often called a *global invariant*.

Atomic sections

Used for synchronization of processes

• General form:

$$\langle await(B) S \rangle$$

- B: Synchronization condition
- Executed atomically when B is true
- Unconditional critical section (B is true):

$$\langle S \rangle$$
 (1)

S executed atomically

Conditional synchronization: ¹⁵

$$|\operatorname{await}(B)\rangle$$
 (2)

Atomic sections

Used for synchronization of processes

• General form:

$$\langle await(B) S \rangle$$

- B: Synchronization condition
- Executed atomically when B is true
- Unconditional critical section (B is true):

$$\langle S \rangle$$
 (1)

S executed atomically

Conditional synchronization:¹⁵

$$\langle await(B) \rangle$$
 (2)

Atomic sections

Used for synchronization of processes

• General form:

$$\langle \mathtt{await}(B) | S \rangle$$

- B: Synchronization condition
- Executed atomically when B is true
- Unconditional critical section (B is true):

$$\langle S \rangle$$
 (1)

S executed atomically

Conditional synchronization:¹⁵

$$\langle await(B) \rangle$$
 (2)

 $^{^{15}}$ We also use then just **await** (B) or maybe **await** B. But also in this case we assume that B is evaluated atomically.

Critical sections using locks

Safety properties:

- Mutex
- Absence of deadlock
- Absence of unnecessary waiting

What about taking away the angle brackets <...>

Critical sections using locks

```
bool lock = false;

process [i=1 to n] {
    while (true) {
        < await (¬ lock) lock := true >;
        CS;
        lock := false;
        non CS;
    }
}
```

Safety properties:

- Mutex
- Absence of deadlock
- Absence of unnecessary waiting

What about taking away the angle brackets < ... > ?

Critical sections using locks

```
bool lock = false;

process [i=1 to n] {
    while (true) {
        < await (¬ lock) lock := true >;
        CS;
        lock := false;
        non CS;
}
```

Safety properties:

- Mutex
- Absence of deadlock
- Absence of unnecessary waiting

What about taking away the angle brackets <...>?

Test & Set is a method/pattern for implementing conditional atomic action:

Effect of TS(lock)

- side effect: The variable lock will always have value true after TS(lock),
- returned value: true or false, depending on the original state of lock
- exists as an atomic HW instruction on many machines.

Test & Set is a method/pattern for implementing conditional atomic action:

Effect of TS(lock)

- side effect: The variable lock will always have value true after TS(lock),
- returned value: true or false, depending on the original state of lock
- exists as an atomic HW instruction on many machines.

Critical section with TS and spin-lock

Spin lock:

2

5

6

7

8 9 10

```
bool lock := false;

process p [i=1 to n] {
    while (true) {
        while (TS(lock)) {skip}; # entry protocol
        CS
        lock := false; # exit protocol
        non-CS
    }
}
```

NB:

Safety: Mutex, absence of deadlock and of unnecessary delay.

Strong fairness needed to guarantee eventual entry for a process

Variable lock becomes a hotspot!

Critical section with TS and spin-lock

Spin lock:

```
bool lock := false:
2
3
      process p [i=1 to n] {
        while (true) {
          while (TS(lock)) {skip};
                                           # entry protocol
5
          CS
6
          lock := false;
7
                                            # exit protocol
          non-CS
8
10
```

NB:

Safety: Mutex, absence of deadlock and of unnecessary delay.

Strong fairness needed to guarantee eventual entry for a process

Variable lock becomes a hotspot!

Critical section with TS and spin-lock

Spin lock:

```
bool lock := false:
2
3
      process p [i=1 to n] {
        while (true) {
          while (TS(lock)) {skip};
                                           # entry protocol
5
          CS
6
          lock := false;
7
                                            # exit protocol
          non-CS
8
10
```

NB:

Safety: Mutex, absence of deadlock and of unnecessary delay.

Strong fairness needed to guarantee eventual entry for a process

Variable lock becomes a hotspot!

Better safe than sorry?

What about *double-checking* in the entry protocol whether it is *really, really* safe to enter?

```
bool lock := false;

process p[i = i to n] {
    while (true) {
        while (lock) {skip}; # additional spin-lock check
        while (TS(lock)) {skip};

        CS;
        lock := false;
        non-CS
    }
}
```

Does that make sense?

Better safe than sorry?

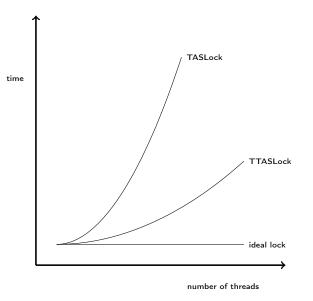

What about *double-checking* in the entry protocol whether it is *really, really* safe to enter?

```
bool lock := false;

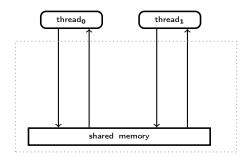

process p[i = i to n] {
    while (true) {
        while (lock) {skip};  # additional spin lock check
        while (TS(lock)) {
            while (lock) {skip}}; # + more inside the TAS loop
        CS;
        lock := false;
        non-CS
    }
}
```

Does that make sense?

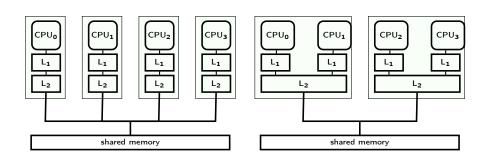

Multiprocessor performance under load (contention)

A glance at HW for shared memory

A glance at HW for shared memory

Test and test & set

- Test-and-set operation:
 - (Powerful) HW instruction for synchronization
 - Accesses main memory (and involves "cache synchronization")
 - Much slower than cache access
- Spin-loops: faster than TAS loops
- "Double-checked locking": important design pattern/programming idiom for efficient CS (under certain architectures)¹⁶

Implementing await-statements

Let CSentry and CSexit implement entry- and exit-protocols to the critical section.

Then the statement < S;> can be implemented by

```
CSentry; S; CSexit;
```

Implementation of conditional critical section < await (B) S;> :

```
CSentry;
while (!B) {CSexit ; CSentry};
S;
CSexit;
```

The implementation can be optimized with Delay between the exit and entry in the body of the while statement.

Implementing await-statements

Let CSentry and CSexit implement entry- and exit-protocols to the critical section.

Then the statement < S;> can be implemented by

CSentry; S; CSexit;

Implementation of conditional critical section < await (B) S;> :

```
CSentry;
while (!B) {CSexit; CSentry};
S;
CSexit;
```

The implementation can be optimized with Delay between the exit and entry in the body of the while statement.

Implementing await-statements

Let CSentry and CSexit implement entry- and exit-protocols to the critical section.

Then the statement $\langle S; \rangle$ can be implemented by

```
CSentry; S; CSexit;
```

Implementation of *conditional critical section* < **await** (B) S;> :

```
CSentry;
while (!B) {CSexit; CSentry};
S;
CSexit;
```

The implementation can be optimized with Delay between the exit and entry in the body of the **while** statement.

Liveness properties

So far: no(!) solution for "Eventual Entry"-property, except the very first (which did not satisfy "Absence of Unnecessary Delay").

- Liveness: Something good will happen
- Typical example for sequential programs: (esp. in our context)
 Program termination¹⁷
- Typical example for parallel programs:
 A given process will eventually enter the critical section

Note: For parallel processes, *liveness is affected by the scheduling strategies.*

Note: For parallel processes, *liveness is affected by the scheduling strategies.*

¹⁷In the first version of the slides of lecture 1, termination was defined misleadingly.

- A command is enabled in a state if the statement can in principle be executed next
- Concurrent programs: often more than 1 statement enabled!

Scheduling: resolving non-determinism

A strategy such that for all points in an execution: if there is more than one statement enabled, pick one of them.

Fairness

- A command is enabled in a state if the statement can in principle be executed next
- Concurrent programs: often more than 1 statement enabled!

```
bool x := true;
co while (x){ skip }; || x := false co
```

Scheduling: resolving non-determinism

A strategy such that for all points in an execution: if there is more than one statement enabled, pick one of them.

Fairness

Fairness

- Fairness: how to pick among enabled actions without being "passed over" indefinitely
- Which actions in our language are potentially non-enabled? ¹⁸
- Possible status changes:
 - disabled \rightarrow enabled (of course),
 - ullet but also enabled o disabled
- Differently "powerful" forms of fairness: guarantee of progress
 - 1. for actions that are always enabled
 - 2. for those that stay enabled
 - 3. for those whose enabledness show "on-off" behavior

 $^{^{18}}$ provided the control-flow/program pointer stands in from took beam. otin > 18

- Fairness: how to pick among enabled actions without being "passed over" indefinitely

A scheduling strategy is *unconditionally fair* if each unconditional atomic action which can be chosen, will eventually be chosen.

```
bool x := true;
co while (x){ skip }; || x := false co
```

A scheduling strategy is *unconditionally fair* if each unconditional atomic action which can be chosen, will eventually be chosen.

```
bool x := true;

co while (x){ skip }; || x := false co
```

A scheduling strategy is *unconditionally fair* if each unconditional atomic action which can be chosen, will eventually be chosen.

```
bool x := true;

co while (x){ skip }; || x := false co
```

- x := false is unconditional
- ⇒ The action will eventually be chosen
 - This guarantees termination
 - Example: "Round robin" execution
 - Note: if-then-else, while (b); are not conditional atomic statements!

A scheduling strategy is *unconditionally fair* if each unconditional atomic action which can be chosen, will eventually be chosen.

```
1 | bool x := true;
2 | co while (x){ skip }; || x := false co
```

- x := false is unconditional
- ⇒ The action will eventually be chosen
 - This guarantees termination
 - Example: "Round robin" execution
 - Note: if-then-else, while (b); are not conditional atomic statements!

A scheduling strategy is *unconditionally fair* if each unconditional atomic action which can be chosen, will eventually be chosen.

```
bool x := true;
co while (x){ skip }; || x := false co
```

- x := false is unconditional
- ⇒ The action will eventually be chosen
 - This guarantees termination
 - Example: "Round robin" execution
 - Note: if-then-else, while (b); are not conditional atomic statements!

Weak fairness

Weak fairness

A scheduling strategy is weakly fair if

- it is unconditionally fair
- every conditional atomic action will eventually be chosen, assuming that the condition becomes true and thereafter remains true until the action is executed.

Example:

```
bool x = true, int y = 0;
co while (x) y = y + 1; || < await y \ge 10; > x = false; oc
```

Weak fairness

Weak fairness

A scheduling strategy is weakly fair if

- it is unconditionally fair
- every conditional atomic action will eventually be chosen, assuming that the condition becomes true and thereafter remains true until the action is executed.

Example:

```
bool x = \text{true}, int y = 0;
co while (x) y = y + 1; || < await y \ge 10; > x = \text{false}; oc
```

Weak fairness

A scheduling strategy is weakly fair if

- it is unconditionally fair
- every conditional atomic action will eventually be chosen, assuming that the condition becomes true and thereafter remains true until the action is executed.

Example:

```
\begin{array}{|c|c|c|c|c|} \hline \textbf{bool} \ \times = \ \textbf{true} \ , \ \ \textbf{int} \ \ y = 0; \\ \hline \textbf{co while} \ \ (\times) \ \ y = y + 1; \ \ |\ | < \ \textbf{await} \ \ y \geq 10; \ > \times = \ \textbf{false} \ ; \ \ \textbf{oc} \end{array}
```

- ullet When y \geq 10 becomes true, this condition remains true
- This ensures termination of the program
- Example: Round robin execution

Strong fairness

Example

Strong fairness

Example

Definition (Strongly fair scheduling strategy)

- unconditionally fair and
- each conditional atomic action will eventually be chosen, if the condition is true infinitely often.

Strong fairness

Example

Definition (Strongly fair scheduling strategy)

- unconditionally fair and
- each conditional atomic action will eventually be chosen, if the condition is true infinitely often.

For the example:

- under strong fairness: y true ∞ -often \Rightarrow termination
- under weak fairness: non-termination possible

Fairness for critical sections using locks

The CS solutions shown need to assume strong fairness to guarantee liveness, i.e., access for a given process (i):

- Steady inflow of processes which want the lock
- value of lock alternates (infinitely often) between true and false
- Weak fairness:
 Process i can read lock only when the value is false
- Strong fairness:
 Guarantees that i eventually sees that lock is true

Difficult: to make a scheduling strategy that is both practical and strongly fair.

We look at CS solutions where access is guaranteed for *weakly* fair strategies

Fairness for critical sections using locks

Fair solutions to the CS problem

- Tie-Breaker Algorithm
- Ticket Algorithm
- The book also describes the bakery algorithm

- Requires no special machine instruction (like TS)
- We will look at the solution for two processes
- Each process has a private lock
- Each process sets its lock in the entry protocol
- The private lock is read, but is not changed by the other process

- Requires no special machine instruction (like TS)
- We will look at the solution for two processes
- Each process has a private lock
- Each process sets its lock in the entry protocol
- The private lock is read, but is not changed by the other process

- Add new variable: last

```
in1 := false, in2 := false; int last
```

Even if the variables in1, in2 and last can change the value while a wait-condition evaluates to true, the wait condition will remain true.

p1 sees that the wait-condition is true:

- in2 = false
 - in2 can eventually become true,
 but then p2 must also set last to 2
 - Then the wait-condition to p1 still holds
- last = 2
 - Then last = 2 will hold until p1 has executed

Thus we can replace the await-statement with a while-loop

Even if the variables in1, in2 and last can change the value while a wait-condition evaluates to true, the wait condition will remain true.

p1 sees that the wait-condition is true:

- in2 = false
 - in2 can eventually become true,
 but then p2 must also set last to 2
 - Then the wait-condition to p1 still holds
- last = 2
 - Then last = 2 will hold until p1 has executed

Thus we can replace the await-statement with a while-loop

Ticket algorithm

Scalability: If the Tie-Breaker algorithm is scaled up to n processes, we get a loop with n-1 2-process Tie-Breaker algorithms.

The *ticket algorithm* provides a simpler solution to the CS problem for *n* processes.

- Works like the "take a number" queue at the post office (with one loop)
- A customer (process) which comes in takes a number which is higher than the number of all others who are waiting
- The customer is served when a ticket window is available and the customer has the lowest ticket number.

Ticket algorithm

- await-statement: can be implemented as while-loop
- Some machines have an instruction fetch-and-add (FA)
 FA(var, incr):< int tmp := var; var := var + incr; return tmp;>

Ticket algorithm: Sketch (*n* processes)

```
int number := 1; next := 1; turn [1:n] := ([n] \ 0);
2
3
    process [i = 1 \text{ to } n] {
      while (true) {
4
5
        < turn[i] := number; number := number +1 >;
        < await (turn[i] = next)>;
6
7
        CS
8
        <next = next + 1>;
        non-CS
9
10
11
```

- The first line in the loop must be performed atomically!
- await-statement: can be implemented as while-loop
- Some machines have an instruction fetch-and-add (FA):
 FA(var, incr):< int tmp := var; var := var + incr; return tmp;>

Ticket algorithm: Implementation

```
int number := 1; next := 1; turn [1:n] := ([n] \ 0);
2
3
    process [i = 1 \text{ to } n] {
      while (true) {
4
        turn[i] := FA(number, 1);
5
        while (turn [i] != next) {skip};
6
7
        CS
8
        next := next + 1;
        non-CS
10
11
```

```
FA(var, incr): < int tmp := var; var := var + incr; return tmp; >
```

Without this instruction, we use an extra CS:20

```
CSentry; turn[i]=number; number = number + 1; CSexit
```

Problem with fairness for CS. Solved with the bakery algorithm (see book).

²⁰Why?

Ticket algorithm: Implementation

```
int number := 1; next := 1; turn [1:n] := ([n] \ 0);
2
3
    process [i = 1 \text{ to } n] {
      while (true) {
4
        turn[i] := FA(number, 1);
5
        while (turn [i] != next) {skip};
6
7
        CS
8
        next := next + 1;
        non-CS
10

Invariants

- What is the global invariant for the ticket algorithm?
- What is the local invariant for process is

Invariants

• What is the global invariant for the ticket algorithm?

0 < next≤number

What is the local invariant for process i:

Invariants

• What is the global invariant for the ticket algorithm?

0 < next<number

• What is the *local* invariant for process *i*:

Invariants

• What is the global invariant for the ticket algorithm?

```
0 < next<number
```

- What is the *local* invariant for process *i*:
 - turn[i] < number
 - if p[i] is in the CS then turn[i] == next.

Invariants

• What is the *global* invariant for the ticket algorithm?

```
0 < next<number
```

- What is the *local* invariant for process *i*:
 - turn[i] < number
 - if p[i] is in the CS then turn[i] == next.
- for pairs of processes $i \neq j$:

```
if turn[i] > 0 then turn[j] \neq turn[i]
```

Invariants

• What is the global invariant for the ticket algorithm?

- What is the *local* invariant for process *i*:
 - turn[i] < number
 - if p[i] is in the CS then turn[i] == next.
- for pairs of processes $i \neq j$:

if
$$turn[i] > 0$$
 then $turn[j] \neq turn[i]$

This holds initially, and is preserved by all atomic statements.

Barrier synchronization

- Computation of disjoint parts in parallel (e.g. array elements).
- Processes go into a loop where each iteration is dependent on the results of the previous.

```
process Worker[i=1 to n] {
   while (true) {
    task i;
   wait until all n tasks are done # barrier
}
}
```

All processes must reach the barrier ("join") before any can continue.

Barrier synchronization

- Computation of disjoint parts in parallel (e.g. array elements).
- Processes go into a loop where each iteration is dependent on the results of the previous.

```
process Worker[i=1 to n] {
    while (true) {
       task i;
       wait until all n tasks are done # barrier
    }
}
```

All processes must reach the barrier ("join") before any can continue.

Barrier synchronization

- Computation of disjoint parts in parallel (e.g. array elements).
- Processes go into a loop where each iteration is dependent on the results of the previous.

```
process Worker[i=1 to n] {
    while (true) {
       task i;
       wait until all n tasks are done # barrier
    }
}
```

All processes must reach the barrier ("join") before any can continue.

A number of processes will synchronize the end of their tasks. Synchronization can be implemented with a *shared counter*:

Can be implemented using the FA instruction.

Disadvantages:

- count must be reset between each iteration.
- Must be updated using atomic operations.
- Inefficient: Many processes read and write count concurrently.

Shared counter

A number of processes will synchronize the end of their tasks. Synchronization can be implemented with a *shared counter*:

```
int count := 0;
process Worker[i=1 to n] {
    while (true) {
        task i;
        < count := count+1>;
        < await(count=n)>;
    }
}
```

Can be implemented using the FA instruction.

Disadvantages:

- count must be reset between each iteration.
- Must be updated using atomic operations.
- Inefficient: Many processes read and write count concurrently.

Shared counter

A number of processes will synchronize the end of their tasks. Synchronization can be implemented with a *shared counter*:

Can be implemented using the FA instruction.

Disadvantages

- count must be reset between each iteration.
- Must be updated using atomic operations.
- Inefficient: Many processes read and write count concurrently.

A number of processes will synchronize the end of their tasks. Synchronization can be implemented with a *shared counter*:

Can be implemented using the FA instruction.

Disadvantages:

- count must be reset between each iteration.
- Must be updated using atomic operations.
- Inefficient: Many processes read and write count concurrently.

Goal: Avoid too many read- and write-operations on one variable!!

Divides shared counter into several local variables

```
Worker[i]:
    arrive[i] = 1;
    < await (continue[i] == 1);>

Coordinator:
    for [i=1 to n] < await (arrive[i]==1);>
    for [i=1 to n] continue[i] = 1;
```

NB: In a loop, the flags must be cleared before the next iteration!

Flag synchronization principles:

- 1. The process waiting for a flag is the one to reset that flag
- 2. A flag will not be set before it is reset

Goal: Avoid too many read- and write-operations on one variable!!

Divides shared counter into several local variables.

```
Worker[i]:
    arrive[i] = 1;
    < await (continue[i] == 1);>

Coordinator:
    for [i=1 to n] < await (arrive[i]==1);>
    for [i=1 to n] continue[i] = 1;
```

NB: In a loop, the flags must be cleared before the next iteration!

- 2. A flag will not be set before it is reset

Synchronization using flags

Both arrays continue and arrived are initialized to 0.

```
process Coordinator {
  while (true) {
    for [i = 1 to n] {
        <await (arrived[i] = 1)>;
        arrived[i] := 0
        };
    for [i = 1 to n] {
        continue[i] := 1
    }
}
```

Synchronization using flags

Both arrays continue and arrived are initialized to 0.

```
process Worker [i = 1 to n] {
    while (true) {
        code to implement task i;
        arrive[i] := 1;
        < await (continue[i] := 1);
        continue := 0;
    }
}</pre>
```

```
process Coordinator {
  while (true) {
    for [i = 1 to n] {
        <await (arrived[i] = 1)>;
        arrived[i] := 0
        };
    for [i = 1 to n] {
        continue[i] := 1
        }
    }
}
```

Synchronization using flags

Both arrays continue and arrived are initialized to 0.

```
process Coordinator {
  while (true) {
    for [i = 1 to n] {
        <await (arrived[i] = 1)>;
        arrived[i] := 0
        };
    for [i = 1 to n] {
        continue[i] := 1
        }
    }
}
```

Combined barriers

- The roles of the Worker and Coordinator processes can be combined.
- In a *combining tree barrier* the processes are organized in a tree structure. The processes signal *arrive* upwards in the tree and *continue* downwards in the tree.

```
bool lock = false;
```

Entry: <await (!lock) lock = true>

Critical section

Exit: < lock = false; >

Spin lock implementation of entry: while (TS(lock)) skip

Drawbacks:

- Busy waiting protocols are often complicated
- Inefficient if there are fever processors than processes
 - Should not waste time executing a skip loop!
- No clear distinction between variables used for synchronization and computation!

Desirable to have a special tools for synchronization protocols

Next week we will do better: semaphores!

Semaphores

INF4140 - Models of concurrency Semaphores, lecture 3

Høsten 2014

12 September, 2014

Overview

- Last lecture: Locks and Barriers (complex techniques)
 - No clear separation between variables for synchronization and variables to compute results
 - Busy waiting
- This lecture: Semaphores (synchronization tool)
 - Used easily for mutual exclusion and condition synchronization.
 - A way to implement signaling and (scheduling).
 - Can be implemented in many ways.

Outline

- Semaphores: Syntax and semantics
- Synchronization examples:
 - Mutual exclusion (Critical Section)
 - Barriers (signaling events)
 - Producers and consumers (split binary semaphores)
 - Bounded buffer: resource counting
 - Dining philosophers: mutual exclusion deadlock
 - Readers and writers: (condition synchronization passing the baton

Semaphores

- Introduced by Dijkstra in 1968
- "inspired" by railroad traffic synchronization
- railroad semaphore indicates whether the track ahead is clear or occupied by another train

Properties

- Semaphores in concurrent programs: work similarly
- Used to implement
 - mutex and
 - condition synchronization
- Included in most standard libraries for concurrent programming
- also: system calls in e.g., Linux kernel, similar in Windows etc.

Concept

- semaphore: special kind of shared program variable (with built-in sync. power)
- value of a semaphore: a non-negative integer
- can *only* be manipulated by two atomic operations:²¹

P and V

- P: (Passeren) Wait for signal want to pass
 - effect: wait until the value is greater than zero, and decrease the value by one
- V: (Vrijgeven) Signal an event release
 - effect: increase the value by one
- nowadays, for libraries or sys-calls: other names are preferred (up/down, wait/signal, . . .)
- different "flavors" of semaphores (binary vs. counting)
- a mutex: often (basically) a synonym for binary semaphore

²¹There are different stories about what Dijkstra actually wanted V and P to stand for

Syntax and semantics

- declaration of semaphores:
 - sem s; default initial value is zero
 - sem s := 1;
 - sem s[4] := ([4] 1);
- semantics²² (via "implementation"):

$$\langle \mathtt{await}(s>0) \ s := s-1 \rangle$$

V-operation V(s)

$$\langle s := s + 1 \rangle$$

Important: No direct access to the value of a semaphore.

E.g. a test like

if
$$(s = 1)$$
 then else

is seriously not allowed!

²²meaning

Kinds of semaphores

Kinds of semaphores

General semaphore: possible values — all non-negative integers

Binary semaphore: possible values — 0 and 1

Fairness

- as for await-statements.
- In most languages: FIFO ("waiting queue"): processes delayed while executing P-operations are awaken in the order they where delayed

Example: Mutual exclusion (critical section)

Mutex²³ implemented by a binary semaphore

Note:

- The semaphore is initially 1
- ullet Always P before V o (used as) binary semaphore

²³As mentioned: "mutex" is also used to refer to a data-structure, basically the same as binary semaphore itself.

Example: Barrier synchronization

Semaphores may be used for signaling events

Note:

- signalling semaphores: usually initialized to 0 and
- signal with a V and then wait with a P

Split binary semaphores

split binary semaphore

A set of semaphores, whose sum ≤ 1

mutex by split binary semaphores

- initialization: one of the semaphores =1, all others =0
- discipline: all processes call P on a semaphore, before calling V on (another) semaphore
- \Rightarrow code between the P and the V
 - all semaphores = 0
 - code executed in mutex

Example: Producer/consumer with split binary semaphores

```
T buf; # one element buffer, some type T
sem empty := 1;
sem full := 0;
```

```
process Producer {
    while (true) {
        P(empty);
        buff := data;
        V(full);
    }
}
```

```
process Consumer {
    while (true) {
        P(full);
        buff := data;
        V(empty);
    }
}
```

Note:

- remember also P/C with await + exercise 1
- empty and full are both binary semaphores, together they form a split binary semaphore.
- solution works with several producers/consumers

Increasing buffer capacity

- previous example: strong coupling, the producer must wait for the consumer to empty the buffer before it can produce a new entry.
- easy generalization: buffer of size n.
- loose coupling/asynchronous communication ⇒ "buffering"
 - ring-buffer, typically represented
 - by an array
 - + two integers rear and front.
 - semaphores to keep track of the number of free/used slots

Increasing buffer capacity

- previous example: strong coupling, the producer must wait for the consumer to empty the buffer before it can produce a new entry.
- easy generalization: buffer of size n.
- loose coupling/asynchronous communication ⇒ "buffering"
 - ring-buffer, typically represented
 - by an array
 - + two integers rear and front.
 - semaphores to keep track of the number of free/used slots
 ⇒general semaphore

Producer/consumer: increased buffer capacity

```
T buf[n] # array, elements of type T

int front := 0, rear := 0; # ''pointers''

sem empty := n,

sem full = 0;
```

```
process Producer {
    while (true) {
        P(empty);
        buff[rear] := data;
        rear := (rear + 1) % n;
        V(full);
    }
}
```

```
process Consumer {
    while (true) {
        P(full);
        result := buff[front];
        front := (front + 1) % n
        V(empty);
    }
}
```

Producer/consumer: increased buffer capacity

```
T buf[n] # array, elements of type T

int front := 0, rear := 0; # ''pointers''

sem empty := n,

sem full = 0;
```

```
process Producer {
    while (true) {
        P(empty);
        buff[rear] := data;
        rear := (rear + 1) % n;
        V(full);
    }
}
process Consumer {
    while (true) {
        P(full);
        result := buff[front];
        front := (front + 1) % n
        V(empty);
    }
}

P(full);

front := (front + 1) % n
        V(empty);
}
}
```

several producers or consumers?

Increasing the number of processes

- several producers and consumers.
- New synchronization problems:
 - Avoid that two producers deposits to buf [rear] before rear is updated
 - Avoid that two consumers fetches from buf[front] before front is updated.
- Solution: additionally 2 binary semaphores for protection
 - mutexDeposit to deny two producers to deposit to the buffer at the same time.
 - mutexFetch to deny two consumers to fetch from the buffer at the same time.

Example: Producer/consumer with several processes

```
T buf[n] # array, elem's of type T int front := 0, rear := 0; # ''pointers'' sem empty := n, sem full = 0; sem mutexDeposit, mutexFetch := 1; # protect the data stuct.
```

```
process Producer {
    while (true) {
        P(empty);
        P(mutexDeposit);
        buff[rear] := data;
        rear := (rear + 1) % n;
        V(mutexDeposit);
        V(full);
        }
        }
    }
}
```

```
process Consumer {
  while (true) {
    P(full);
    P(mutexFetch);
    result := buff[front];
    front := (front + 1) % n
    V(mutexFetch);
    V(empty);
  }
}
```

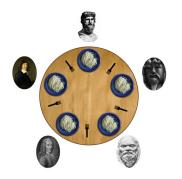

Problem: Dining philosophers introduction

²⁴image from wikipedia.org

Problem: Dining philosophers introduction

- famous sync. problem (Dijkstra)
- Five philosophers sit around a circular table.
- one fork placed between each pair of philosophers
- philosophers alternates between thinking and eating
- philosopher needs two forks to eat (and none for thinking)

²⁴image from wikipedia.org

Dining philosophers: sketch

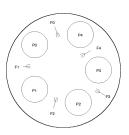

```
process Philosopher [i = 0 to 4] {
    while true {
        think;
        acquire forks;
        eat;
        release forks;
    }
}
```

now: program the actions acquire forks and release forks

Dining philosophers: 1st attempt

- forks as semaphores
- let the philosophers pick up the left fork first

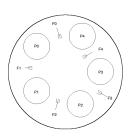

```
process Philosopher [i = 0 to 4] {
   while true {
    think;
   acquire forks;
   eat;
   release forks;
}
```

Dining philosophers: 1st attempt

- forks as semaphores
- let the philosophers pick up the left fork first

```
sem fork [5] := ([5] 1);
    process Philosopher [i = 0 \text{ to } 4] {
2
      while true {
3
         think;
4
        P(fork[i];
5
        P(fork[(i+1)\%5]);
6
         eat:
7
        V(fork[i];
8
        V(fork[(i+1)\%5]);
9
```

ok solution?

Example: Dining philosophers 2nd attempt

breaking the symmetry

To avoid deadlock, let 1 philospher (say 4) grab the right fork first

```
process Philosopher [i = 0 to 3] {
    while true {
        think;
        P(fork[i];
        P(fork[(i+1)%5]);
        eat;
        V(fork[i];
        V(fork[(i+1)%5]);
        }
}
```

```
process Philosopher4 {
    while true {
        think;
        P(fork [4];
        P(fork [0]);
        eat;
        V(fork [4];
        V(fork [0]);
    }
}
```

Example: Dining philosophers 2nd attempt

breaking the symmetry

To avoid deadlock, let 1 philospher (say 4) grab the right fork first

```
process Philosopher [i = 0 to 3] {
    while true {
        think;
        P(fork[i];
        P(fork[(i+1)%5]);
        eat;
        V(fork[(i+1)%5]);
        }
        V(fork[(i+1)%5]);
        }
}
```

```
process Philosopher4 {
    while true {
        think;
        P(fork [0]);
        P(fork [4];
        eat;
        V(fork [4];
        V(fork [0]);
      }
}
```

Dining philosphers

- important illustration of problems with concurrency:
 - deadlock
 - but also other aspects: liveness and fairness etc.
- resource access
- connection to mutex/critical sections

Example: Readers/Writers overview

- Classical synchronization problem
- Reader and writer processes, sharing access to a "database"
 - readers: read-only from the database
 - writers: update (and read from) the database

Example: Readers/Writers overview

- Classical synchronization problem
- Reader and writer processes, sharing access to a "database"
 - readers: read-only from the database
 - writers: update (and read from) the database
- R/R access unproblematic, W/W or W/R: interference
 - writers need mutually exclusive access
 - When no writers have access, many readers may access the database

Readers/Writers approaches

- Dining philosophers: Pair of processes compete for access to "forks"
- Readers/writers: Different important classes of processes competes for access to the database
 - Readers compete with writers
 - Writers compete both with readers and other writers
- General synchronization problem:
 - readers: must wait until no writers are active in DB
 - writers: must wait until no readers or writers are active in DB
- here: two different approaches
 - 1. Mutex: easy to implement, but "unfair"
 - 2. Condition synchronization:
 - Using a split binary semaphore
 - Easy to adapt to different scheduling strategies

Readers/writers with mutex (1)

sem rw := 1

```
process Writer [i=1 to N] {
   while (true) {
     ...
   P(rw);
   write to DB

   V(rw);
  }
}
```

Readers/writers with mutex (1)

```
sem rw := 1
```

```
process Writer [i=1 to N] {
   while (true) {
        ...
        P(rw);
        write to DB

        V(rw);
    }
}
```

- safety ok
- but: unnessessarily cautious
- We want more than one reader simultaneously.

Readers/writers with mutex (2)

Initially:

```
int nr := 0; # nunber of active readers
sem rw := 1 # lock for reader/writer mutex
```

Readers/writers with mutex (2)

Initially:

```
int nr := 0; # nunber of active readers
sem rw := 1 # lock for reader/writer mutex
```

```
process Writer [i=1 \text{ to } N] {
  while (true) {
    P(rw);
   write to DB
    V(rw);
```

Semaphore inside await statement? Don't try that at home.

"Reader's preference"

Readers/writers with condition synchronization: overview

- previous mutex solution solved two separate synchronization problems
 - Readers and. writers for access to the database
 - Reader vs. reader for access to the counter
- Now: a solution based on condition synchronization

reasonable invariant^a

- ^a2nd point: technically, not an invariant.
- 1. When a writer access the DB, no one else can
- 2. When no writers access the DB, one or more readers may
- introduce two counters:
 - nr: number of active readers
 - nw: number of active writers

The invariant may be:

RW:
$$(nr = 0 \text{ or } nw = 0) \text{ and } nw \leq 1$$

Code for "counting" readers and writers

Reader:

```
< nr := nr + 1; >
read from DB
< nr := nr - 1; >
```

Writer:

```
< nw := nw + 1; >
write to DB
< nw := nw - 1; >
```

- maintain invariant ⇒ add sync-code
- decrease counters: not dangerous
- before increasing though:

```
• before increasing nr: nw = 0
```

• before increasing nw: nr = 0 and nw = 0

condition synchronization: without semaphores

Initially:

```
int nr := 0; # number of active readers
int nw := 0; # number of active writers
sem rw := 1 # lock for reader/writer mutex

## Invariant RW: (nr = 0 or nw = 0) and nw <= 1</pre>
```

condition synchr.: converting to split binary semaphores

implementation of await's: possible via split binary semaphores

 May be used to implement different synchronization problems with different guards B₁, B₂...

General pattern

- entry^a semaphore e, initialized to 1
- For each guard B_i:
 - associate 1 counter and
 - 1 delay-semaphore

both initialized to 0

- semaphore: delay the processes waiting for Bi
- counter: count the number of processes waiting for B_i

^aEntry to the administractive CS's, not entry to data-base access

```
⇒ for readers/writers problem: 3 semaphores and 2 counters:
```

```
sem e = 1;

sem r = 0; int dr = 0;  # condition reader: nw == 0

sem w = 0; int dw = 0;  # condition writer: nr == 0 and nw == 0
```

Condition synchr.: converting to split binary semaphores (2)

- e, r and w form a split binary semaphore.
- All execution paths start with a P-operation and end with a V-operation → Mutex

Signaling

We need a signal mechanism SIGNAL to pick which semaphore to signal.

- SIGNAL: make sure the invariant holds
- \bullet B_i holds when a process enters CR because either:
 - the process checks itself,
 - or
- •

Condition synchr.: converting to split binary semaphores (2)

- e, r and w form a split binary semaphore.
- All execution paths start with a P-operation and end with a V-operation → Mutex

Signaling

We need a signal mechanism SIGNAL to pick which semaphore to signal.

- SIGNAL: make sure the invariant holds
- B_i holds when a process enters CR because either:
 - the process checks itself.
 - or the process is only signaled if B; holds
- and another pitfall:

Condition synchr.: converting to split binary semaphores (2)

- e, r and w form a split binary semaphore.
- All execution paths start with a P-operation and end with a V-operation → Mutex

Signaling

We need a signal mechanism **SIGNAL** to pick which semaphore to signal.

- SIGNAL: make sure the invariant holds
- \bullet B_i holds when a process enters CR because either:
 - the process checks itself,
 - or the process is only signaled if B_i holds
- and another pitfall: Avoid deadlock by checking the counters before the delay semaphores are signaled.
 - r is not signalled (V(r)) unless there is a delayed reader
 - ullet w is not signalled (V(w)) unless there is a delayed writer

Condition synchr.: Reader

Monitors

INF4140 - Models of concurrency Monitors, lecture 4

Høsten 2014

19. Sep 2014

Overview

- Concurrent execution of different processes
- Communication by shared variables
- Processes may interfere

```
x := 0; co x := x + 1 \mid \mid x := x + 2 oc final value of x will be 1, 2, or 3
```

await language – atomic regions

```
x := 0; co \langle x := x + 1 \rangle || \langle x := x + 2 \rangle oc final value of x will be 3
```

special tools for synchronization:

Last week: semaphores

Today: monitors

Outline

- Semaphores: review
- Monitors:
 - Main ideas
 - Syntax and semantics
 - Condition variables
 - Signaling disciplines for monitors
 - Synchronization problems:
 - Bounded buffer
 - Readers/writers
 - Interval timer
 - Shortest-job next scheduling
 - Sleeping barber

Semaphores

- Used as "synchronization variables"
- Declaration: sem s = 1;
- Manipulation: Only two operations, P(s) and V(s)
- Advantage: Separation of business and synchronization code
- Disadvantage: Programming with semaphores can be tricky:
 - Forgotten P or V operations
 - Too many P or V operations
 - They are shared between processes
 - Global knowledge
 - May need to examine all processes to see how a semaphore works

Monitors

Monitor

"Abstract data type + synchronization"

- program modules with more structure than semaphores
- monitor encapsulates data, which can only be observed and modified by the monitor's procedures.
 - contains variables that describe the state
 - variables can be changed only through the available procedures
- implicit mutex: only a procedure may be active at a time.
 - A procedure: mutex access to the data in the monitor
 - 2 procedures in the same monitor: never executed concurrently
- Condition synchronization:²⁵ is given by *condition variables*
- At a lower level of abstraction: monitors can be implemented using locks or semaphores

²⁵block a process until a particular condition holds. $\square \rightarrow \neg \square \rightarrow \neg \square$

Usage

- processs = active ⇔ Monitor: = passive/re-active
- a procedure is *active*, if a statement in the procedure is executed by some process
- all shared variables: inside the monitor
- processes communicate by calling monitor procedures
- processes do not need to know all the implementation details
 - Only the visible effects of the called procedure are important
- the implementation can be changed, if visible effect remains the same
- Monitors and processes can be developed relatively independent ⇒ Easier to understand and develop parallel programs

Syntax & semantics

```
monitor name {
mon. variables # shared global variables
initialization
procedures
}
```

monitor: a form of abstract data type:

• only the procedures' names visible from outside the monitor:

```
call name.opname(arguments)
```

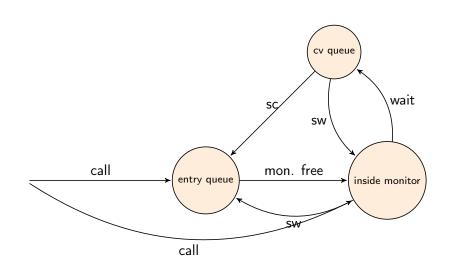

- statements inside a monitor: no access to variables outside the monitor
- monitor variables: initialized before the monitor is used

monitor invariant: used to describe the monitor's inner states

Condition variables

- monitors contain special type of variables: cond (condition)
- used for synchronizaton/to delay processes
- each such variable is associated with a wait condition
- "value" of a condition variable: queue of delayed processes
- value: not directly accessible by programmer
- Instead, manipulate it by special operations

```
cond cv;  # declares a condition variable cv
empty(cv);  # asks if the queue on cv is empty
wait(cv);  # causes the process to wait in the queue to cv
signal(cv);  # wakes up a process in the queue to cv
signal_all(cv);  # wakes up all processes in the queue to cv
```

A monitor with P and V operations:

```
monitor Semaphore { \# monitor invariant: s > 0
     int s := 0 # value of the semaphore
     cond pos;  # wait condition
3
4
5
     procedure Psem() {
6
       while (s=0) { wait (pos) };
7
       s := s - 1
8
9
10
     procedure Vsem() {
11
       s := s+1;
12
       signal (pos);
13
14
15
```

Signaling disciplines

- signal on a condition variable cv roughly has the following effect:
 - empty queue: no effect
 - the process at the head of the queue to cv is woken up
- wait and signal constitute a FIFO signaling strategy
- When a process executes signal(cv), then it is inside the monitor. If a waiting process is woken up, there would be two active processes in the monitor.

2 disciplines to provide mutex:

- Signal and Wait (SW): the signaller waits, and the signalled process gets to execute immediately
- Signal and Continue (SC): the signaller continues, and the signalled process executes later

Is this a FIFO semaphore assuming SW or SC?

```
monitor Semaphore { \# monitor invariant: s > 0
     int s := 0 # value of the semaphore
     cond pos;  # wait condition
3
4
5
     procedure Psem() {
6
       while (s=0) { wait (pos) };
7
       s := s - 1
8
9
10
     procedure Vsem() {
11
       s := s+1;
12
       signal (pos);
13
14
15
```

FIFO semaphore for SW

```
monitor Semaphore { # monitor invariant: s \ge 0
     int s := 0
                # value of the semaphore
     cond pos; # wait condition
3
4
     procedure Psem() {
5
6
       while (s=0) { wait (pos) };
7
       s := s - 1
8
10
     procedure Vsem() {
11
       s := s+1;
12
       signal (pos);
13
14
15
```

FIFO semaphore for SW

```
monitor Semaphore { # monitor invariant: s \ge 0
     int s := 0
                # value of the semaphore
     cond pos; # wait condition
3
4
     procedure Psem() {
5
6
       if (s=0) { wait (pos) };
7
       s := s - 1
8
10
     procedure Vsem() {
11
       s := s+1;
12
       signal (pos);
13
14
15
```

FIFO semaphore

3

5

6

7

8

13 14

15 16

17 18 19 FIFO semaphore with SC: can be achieved by explicit transfer of control inside the monitor (forward the condition).

```
monitor Semaphore fifo \{ \# monitor invariant : s \geq 0 \}
  int s := 0:
                     # value of the semaphore
  cond pos;
                        # wait condition
  procedure Psem() {
    i f
        (s=0)
        wait (pos);
    else
       s := s - 1
  procedure Vsem() {
    i f
       empty (pos)
         s := s + 1
    else
         signal (pos);
```

Bounded buffer synchronization (1)

- buffer of size *n* ("channel", "pipe")
- producer: performs put operations on the buffer.
- consumer: performs get operations on the buffer.
- count: number of items in the buffer
- two access operations ("methods")
 - put operations must wait if buffer full
 - get operations must wait if buffer empty
- assume SC discipline²⁶

Bounded buffer synchronization (2)

- When a process is woken up, it goes back to the monitor's entry queue
 - Competes with other processes for entry to the monitor
 - Arbitrary delay between awakening and start of execution
 - ⇒ re-test the wait condition, when execution starts
 - E.g.: put process wakes up when the buffer is not full
 - Other processes can perform put operations before the awakened process starts up
 - Must therefore re-check that the buffer is not full

Bounded buffer synchronization monitors (3)

```
monitor Bounded Buffer {
  typeT buf[n]; int count := 0;
  cond not_full, not_empty;
  procedure put(typeT data){
     while (count = n) wait(not_full);
     # Put element into buf
     count := count + 1; signal(not_empty);
  procedure get(typeT &result) {
     while (count = 0) wait(not_empty);
     # Get element from buf
     count := count - 1; signal(not_full);
```

Bounded buffer synchronization: client-sides

```
process Producer[i = 1 to M]{
       while (true){
          call Bounded Buffer.put(data);
process Consumer[i = 1 \text{ to } N]
       while (true){
          call Bounded Buffer.get(result);
```

Readers/writers problem

- Reader and writer processes share a common resource ("database")
- Reader's transactions can read data from the DB
- Write transactions can read and update data in the DB
- Assume:
 - DB is initially consistent and that
 - Each transaction, seen in isolation, maintains consistency
- To avoid interference between transactions, we require that
 - writers: exclusive access to the DB.
 - No writer: an arbitrary number of readers can access simultaneously

Monitor solution to the reader/writer problem (2)

- database cannot be encapsulated in a monitor, as the readers will not get shared access
- monitor instead used to give access to the processes
- processes don't enter the critical section (DB) until they have passed the RW_Controller monitor

Monitor procedures:

- request_read: requests read access
- release_read: reader leaves DB
- request_write: requests write access
- release_write: writer leaves DB

Invariants and signalling

Assume that we have two counters as local variables in the monitor:

```
nr — number of readersnw — number of writers
```

Invariant

We want RW to be a monitor invariant

 chose carefully condition variables for "communication" (waiting/signaling)

Let two condition variables oktoread og oktowrite regulate waiting readers and waiting writers, respectively.

Invariants and signalling

Assume that we have two counters as local variables in the monitor:

```
nr — number of readersnw — number of writers
```

Invariant

```
RW: (nr = 0 \text{ or } nw = 0) \text{ and } nw \leq 1
```

We want RW to be a monitor invariant

 chose carefully condition variables for "communication" (waiting/signaling)

Let two condition variables oktoread og oktowrite regulate waiting readers and waiting writers, respectively.

```
monitor RW Controller { \#RW (nr = 0 or nw = 0) and nw \leq 1
 int nr := 0, nw := 0
 cond oktoread; \# signalled when nw = 0
 cond oktowrite: # sig 'ed when nr = 0 and nw = 0
 procedure request read() {
   while (nw > 0) wait(oktoread);
   nr := nr + 1:
 procedure release read() {
    nr := nr - 1;
   if nr = 0 signal (oktowrite);
 procedure request write() {
    while (nr > 0 \text{ or } nw > 0) wait (oktowrite);
   nw := nw + 1:
  procedure release write() {
   nw := nw -1:
    signal(oktowrite); # wake up 1 writer
    signal all(oktoread); # wake up all readers
```

15

16 17

18 19

20 21

22 23

Invariant

- monitor invariant 1: describe the monitor's inner state
- expresses relationship between monitor variables
- maintained by execution of procedures:
 - must hold: after initialization
 - must hold: when a procedure terminates
 - must hold: when we suspend execution due to a call to wait
 - ⇒ can assume that the invariant holds after wait and when a procedure starts
- Should be as strong as possible

Monitor solution to reader/writer problem (6)

```
RW: (nr = 0 \text{ or } nw = 0) \text{ and } nw \leq 1
```

```
procedure request_read() {
      # May assume that the invariant holds here
      while (nw > 0) {
           # the invariant holds here
           wait(oktoread):
           # May assume that the invariant holds here
      }
      # Here, we know that nw = 0...
      nr := nr + 1;
      # ...thus: invariant also holds after increasing nr
```

Time server

- Monitor that enables sleeping for a given amount of time
- Resource: a logical clock (tod)
- Provides two operations:
 - delay(interval) the caller wishes to sleep for interval time
 - tick increments the logical clock with one tick
 Called by the hardware, preferably with high execution priority
- Each process which calls delay computes its own time for wakeup: wake_time := tod + interval;
- Waits as long as tod < wake_time
 - Wait condition is dependent on local variables

Covering condition:

- all processes are woken up when it is possible for some to continue
- Each process checks its condition and sleeps again if this does not hold

Time server: covering condition

Invariant: CLOCK: tod $\geq 0 \land$ tod increases monotonically by 1

```
monitor Timer { int tod = 0; # Time Of Day
    cond check; # signalled when tod is increased

procedure delay(int interval) {
    int wake_time;
    wake_time = tod + interval;
    while (wake_time > tod) wait(check);
}

procedure tick() {
    tod = tod + 1;
    signal_all(check);
}
```

- Not very effective if many processes will wait for a long time
- Can give many false alarms

Prioritized waiting

- Can also give additional argument to wait: wait(cv, rank)
 - Process waits in the queue to cv in ordered by the argument rank.
 - At signal:
 Process with lowest rank is awakened first
- Call to minrank(cv) returns the value of rank to the first process in the queue (with the lowest rank)
 - The queue is not modified (no process is awakened)
- Allows more efficient implementation of Timer

Time server: Prioritized wait

- Uses prioritized waiting to order processes by check
- The process is awakened only when tod ≥ wake_time
- Thus we do not need a while loop for delay

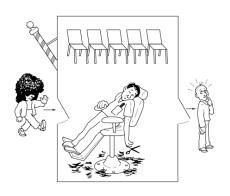

```
monitor Timer {
    int tod = 0; # Invariant: CLOCK
    cond check; # signalled when minrank(check) < tod
    procedure delay(int interval) {
        int wake time;
        wake time := tod + interval;
        if (wake time > tod) wait(check, wake time);
   }
    procedure tick() {
        tod := tod + 1;
        while (!empty(check) && minrank(check) \leq tod)
        signal(check);
```

Shortest-Job-Next allocation

- Competition for a shared resource
- A monitor administrates access to the resource
- Call to request(time)
 - Caller needs access for time interval time
 - If the resource is free: caller gets access directly
- Call to release
 - The resource is released
 - If waiting processes: The resource is allocated to the waiting process with lowest value of time
- Implemented by prioritized wait

Shortest-Job-Next allocation (2)

```
monitor Shortest Job Next {
     bool free = true;
     cond turn;
3
4
     procedure request(int time) {
5
       if (free)
6
         free := false
7
       else
8
         wait (turn, time)
9
10
11
12
      procedure release() {
        if (empty(turn))
13
          free := true;
14
        else
15
          signal (turn);
16
17
```

The story of the sleeping barber

- barbershop: with two doors and some chairs.
- customers: come in through one door and leave through the other. Only one customer sits the he barber chair at a time.
- Without customers: barber sleeps in one of the chairs.
- When a customer arrives and the barber sleeps ⇒ barber is woken up and the customer takes a seat.
- barber busy ⇒ the customer takes a nap
- Once served, barber lets customer out the exit door.
- If there are waiting customers, one of these is woken up.
 Otherwise the barber sleeps again.

Interface

Assume the following *monitor procedures*

Client: get_haircut: called by the customer, returns when haircut is done

Server: barber calls:

- get_next_customer: called by the barber to serve a customer
- finish_haircut: called by the barber to let a customer out of the barbershop

Rendez-vous

Similar to a two-process barrier: *Both* parties must arrive before either can continue.^a

- The barber must wait for a customer
- Customer must wait until the barber is available

The barber can have rendezvous with an arbitrary customer.

^aLater, in the context of message passing, will have a closer look at making rendez-vous synchronization (using channels), but the pattern "2 partners must be present at a point at the same time" is analogous.

Organize the synch.: Identify the synchronization needs

- 1. barber must wait until
 - 1.1 customer sits in chair
 - 1.2 customer left barbershop
- 2. customer must wait until
 - 2.1 the barber is available
 - 2.2 the barber opens the exit door

client perspective:

- two phases (during get_haircut)
 - 1. "entering"
 - trying to get hold of barber,
 - sleep otherwise
 - 2. "leaving":
- between the phases: suspended

Processes signal when one of the wait conditions is satisfied.

Organize the synchronization: state

3 var's to synchronize the processes: barber, chair and open (initially 0)

binary variables, alternating between 0 and 1:

- for entry-rendevouz
 - 1. barber = 1: the barber is ready for a new customer
 - chair = 1: the customer sits in a chair, the barber hasn't begun to work
 - for exit-sync
 - 3. open = 1: exit door is open, the customer has not yet left

Sleeping barber

```
monitor Barber Shop {
     int barber := 0, chair := 0, open := 0;
2
                                \# signalled when barber > 0
3
     cond barber available;
     cond chair occupied;
                          \# signalled when chair > 0
4
                               \# signalled when open > 0
5
     cond door open;
                                  \# signalled when open = 0
     cond customer left;
6
7
8
   procedure get haircut() {
     while (barber = 0) wait(barber available); # RV with barber
9
     barber := barber - 1;
10

```

Program analysis

INF4140 - Models of concurrency Program Analysis, lecture 5

Høsten 2014

26.9.2014

Program correctness

Is my program correct?

Central question for this and the next lecture.

- Does a given program behave as intended?
- Surprising behavior?

$$x := 5; \{ x = 5 \} \langle x := x + 1 \rangle; \{ x = ? \}$$

- clear: x = 5 immediately after first assignment
- Will this still hold when the second assignment is executed?
 - Depends on other processes
- What will be the final value of x?

Today: Basic machinery for program reasoning

Next week: Extending this machinery to the concurrent setting

Concurrent executions

- Concurrent program: several threads operating on (here) shared variables
- Parallel updates to x and y:

$$\operatorname{co} \langle x := x \times 3; \rangle \parallel \langle y := y \times 2; \rangle \operatorname{oc}$$

- Every concurrent execution can be written as a sequence of atomic operations (gives one history)
- Two possible histories for the above program
- Generally, if n processes executes m atomic operations each:

$$\frac{(n*m)!}{m!^n}$$
 If n=3 and m=4: $\frac{(3*4)!}{4!^3} = 34650$

How to verify program properties?

- Testing or debugging increases confidence in the program correctness, but does not guarantee correctness
 - Program testing can be an effective way to show the presence of bugs, but not their absence
- Operational reasoning (exhaustive case analysis) tries all possible executions of a program
- Formal analysis (assertional reasoning) allows to deduce the correctness of a program without executing it
 - Specification of program behavior
 - Formal argument that the specification is correct

- A *state* of a program consists of the values of the program variables at a point in time, example: $\{x = 2 \land y = 3\}$
- The *state space* of a program is given by the different values that the declared variables can take
- Sequential program: one execution thread operates on its own state space
- The state may be changed by assignments ("imperative")

Example

```
\{x = 5 \land y = 5\}x := x * 2; \{x = 10 \land y = 5\}y := y * 2; \{x = 10 \land y = 10\}
```

Executions

• Given program S as sequence S_1 ; S_2 ; ...; S_n ;, starting in a state p_0 :

$$\bullet \xrightarrow{p_0} \boxed{S_1} \xrightarrow{p_1} \boxed{S_2} \xrightarrow{p_2} \dots \xrightarrow{p_{n-1}} \boxed{S_n} \xrightarrow{p_n} \bullet$$

where $p_1, p_2, \dots p_n$ are the different states during execution

- Can be documented by: $\{p_0\}S_1\{p_1\}S_2\{p_2\}\dots\{p_{n-1}\}S_n\{p_n\}$
- p_0, p_n gives an external specification of the program: $\{p_0\}S\{p_n\}$
- We often refer to p_0 as the *initial* state and p_n as the *final* state

Example (from previous slide)

$$\{ x = 5 \land y = 5 \} x := x * 2; y := y * 2; \{ x = 10 \land y = 10 \}$$

Assertions

Want to express more general properties of programs, like

$$\{ x = y \} x := x * 2; y := y * 2; \{ x = y \}$$

- If the assertion x = y holds, when the program starts, x = y will also hold when/if the program terminates
- Does not talk about particular values of x and y, but about relations between their values
- Assertions characterise sets of states

Example

The assertion x = y describes *all* states where the values of x and y are equal, like $\{x = -1 \land y = -1\}, \{x = 1 \land y = 1\}, \dots$

Assertions

 An assertion P can be viewed as a set of states where P is true:

x=y All states where x has the same value as y All states where the value of x is less

or equal to the value of y

 $x = 2 \land y = 3$ Only one state (if x and y are the only variables)

true All states false No state

Example

$$\{x = y\}x := x * 2; \{x = 2 * y\}y := y * 2; \{x = y\}$$

Then this must also hold for particular values of x and y satisfying the initial assertion, like x=y=5

Formal analysis of programs

- Establish program properties, using a system for formal reasoning
- Help in understanding how a program behaves
- Useful for program construction
- Look at logics for formal analysis
- basis of analysis tool

Formal system

- Axioms: Defines the meaning of individual program statements
- Rules: Derive the meaning of a program from the individual statements in the program

Logics and formal systems

Our formal system consists of:

- A set of symbols (constants, variables,...)
- A set of formulas (meaningful combination of symbols)
- A set of axioms (assumed to be true)
- A set of inference rules of the form:

Inference rule

$$\frac{H_1 \quad \dots \quad H_n}{C}$$

- Where each H_i is an assumption, and C is the conclusion
- The conclusion is true if all the assumptions are true
- The inference rules specify how to derive additional true formulas from axioms and other true formulas.

Symbols

- (program + extra) variables: x, y, z, ...
- Relation symbols: \leq, \geq, \dots
- Function symbols: $+, -, \ldots$, and constants $0, 1, 2, \ldots, true, false$
- Equality (also a relation symbol): =

Formulas of first-order logic

Meaningful combination of symbols

Assume that A and B are formulas, then the following are also formulas:

 $\neg A$ means "not A"

 $A \lor B$ means "A or B"

 $A \wedge B$ means "A and B"

 $A \Rightarrow B$ means "A implies B"

If x is a variable and A, the following are formulas:²⁷

 $\forall x : A(x)$ means "A is true for all values of x"

 $\exists x : A(x)$ means "there is (at least) one value of x such that A is true"

Examples of axioms and rules

Typical axioms:

- A ∨ ¬A
- \bullet $A \Rightarrow A$

Typical rules:

$$\frac{A \quad B}{A \wedge B} \text{ And-I} \qquad \frac{A}{A \vee B} \text{ Or-I} \qquad \frac{A \Rightarrow B}{B} \quad A \text{ Or-E}$$

Example

$$\frac{x=5 \qquad y=5}{x=5 \land y=5} \text{ And-I} \qquad \frac{x=5}{x=5 \lor y=5} \text{ Or-I}$$

$$\frac{x \ge 0 \Rightarrow y \ge 0 \qquad x \ge 0}{y \ge 0} \text{ Or-E}$$

Important terms

- Interpretation: describe each formula as either true or false
- Proof: derivation tree where all leaf nodes are axioms
- Theorems: a "formula" derivable in a given proof system
- Soundness (of the logic): If we can prove ("derive") some formula P (in the logic) then P is actually (semantically) true
- Completeness: If a formula *P* is true, it can be proven

Program Logic (PL)

- PL lets us express and prove properties about programs
- Formulas are of the form

"Hoare triple"

$$\{P_1\}S\{P_2\}$$

- *S*: program statement(s)
- P, P_1 , P', Q . . . : assertions over program states (including $\neg, \land, \lor, \exists, \forall$)
- In above triple P_1 : Pre-condition, and P_2 post-condition of S

Example

$$\{ x = y \} x := x * 2; y := y * 2; \{ x = y \}$$

The proof system PL (Hoare logic)

- Express and prove program properties
- {*P*} *S* {*Q*}
 - \bullet P, Q may be seen as a specification of the program S
 - Code analysis by proving the specification (in PL)
 - No need to execute the code in order to do the analysis
 - An interpretation maps triples to true or false
 - $\{x = 0\} x := x + 1; \{x = 1\} \text{ should be } true$
 - $\{x = 0\} x := x + 1; \{x = 0\}$ should be *false*

Reasoning about programs

- Basic idea: *Specify* what the program is supposed to do (preand post-conditions)
- Pre- and post-conditions are given as assertions over the program state
- Use PL for amathematical argument that the program satisfies its specification

Interpretation

Interpretation ("semantics") of triples is related to code execution

Partial correctness interpretation

 $\{P\}$ S $\{Q\}$ is *true*/holds, if the following is the case:

- If the initial state of S satisfies P (P holds for the initial state of S),
- and if S terminates,
- then Q is true in the final state of S

Expresses partial correctness (termination of S is assumed)

Example

```
\{x = y\} x := x * 2; y := y * 2; <math>\{x = y\} is true if the initial state satisfies x = y and, in case the execution terminates, then the final state satisfies x = y
```

^aThus: if S does not terminate, all bets are off...

Some true formulas:

$$\left\{ \begin{array}{l} x = 0 \right\} x := x + 1; \; \left\{ \begin{array}{l} x = 1 \right\} \\ \left\{ \begin{array}{l} x = 4 \right\} x := 5; \; \left\{ \begin{array}{l} x = 5 \right\} \\ \left\{ \begin{array}{l} \text{true} \right\} x := 5; \; \left\{ \begin{array}{l} x = 5 \right\} \\ \left\{ \begin{array}{l} y = 4 \right\} x := 5; \; \left\{ \begin{array}{l} y = 4 \right\} \\ \left\{ \begin{array}{l} x = 4 \right\} x := x + 1; \; \left\{ \begin{array}{l} x = 5 \right\} \\ \left\{ \begin{array}{l} x = a \wedge y = b \right\} x = x + y; \; \left\{ \begin{array}{l} x = a + b \wedge y = b \right\} \\ \left\{ \begin{array}{l} x = 4 \wedge y = 7 \right\} x := x + 1; \; \left\{ \begin{array}{l} x = 5 \wedge y = 7 \right\} \\ \left\{ \begin{array}{l} x = y \right\} x := x + 1; \; \left\{ \begin{array}{l} x = y + 1; \; \left\{ \begin{array}{l} x = y \right\} \end{array} \right. \end{array} \right\} \end{array}$$

Some formulas that are not true:

$$\{ x = 0 \} x := x + 1; \{ x = 0 \}$$

 $\{ x = 4 \} x := 5; \{ x = 4 \}$
 $\{ x = y \} x := x + 1; y := y - 1; \{ x = y \}$
 $\{ x > y \} x := x + 1; y := y + 1; \{ x < y \}$

- The interpretation of $\{P\}$ S $\{Q\}$ assumes/ignores termination of S, termination is not proven.
- The assertions (P, Q) express safety properties
- The pre- and postconditions restrict possible states

```
{ P } S { false } 
{ P } S { true } 
{ true } S { Q } 
{ false } S { Q }
```

- The interpretation of $\{P\}$ S $\{Q\}$ assumes/ignores termination of S, termination is not proven.
- The assertions (P, Q) express safety properties
- The pre- and postconditions restrict possible states

```
\{P\} S \{false\} S does not terminate \{P\} S \{true\} \{true\} S \{Q\} \}
```

- The interpretation of $\{P\}$ S $\{Q\}$ assumes/ignores termination of S, termination is not proven.
- The assertions (P, Q) express safety properties
- The pre- and postconditions restrict possible states

```
\{P\} S \{ false \} S does not terminate \{P\} S \{ true \} trivially true \{ true \} S \{ Q \}
```

- The interpretation of $\{P\}$ S $\{Q\}$ assumes/ignores termination of S, termination is not proven.
- The assertions (P, Q) express safety properties
- The pre- and postconditions restrict possible states

```
\{P\} S \{false\} S \text{ does not terminate}
\{P\} S \{true\} \text{ trivially true}
\{true\} S \{Q\} Q \text{ holds after } S \text{ in any case}
\{false\} S \{Q\}
```

- The interpretation of $\{P\}$ S $\{Q\}$ assumes/ignores termination of S, termination is not proven.
- The assertions (P, Q) express safety properties
- The pre- and postconditions restrict possible states

```
\{P\} S \{false\} S \text{ does not terminate}
\{P\} S \{true\} \text{ trivially true}
\{true\} S \{Q\} Q \text{ holds after } S \text{ in any case}
\{false\} S \{Q\} \text{ trivially true}
```

Proof system PL

A proof system consists of *axioms* and *rules* here: structural analysis of programs

- Axioms for basic statements:
 - x := e, skip,...
- Rules for composed statements:
 - $S_1; S_2$, if, while, await, co...oc, ...

Formulas in PL

- formulas = triples
- theorems = derivable formulas
- hopefully: all derivable formulas are also "really" (= semantically) true
- derivation: starting from axioms, using derivation rules

•

$$H_1$$
 H_2 ... H_n

axioms: can be seen as rules without premises

Soundness

If a triple $\{P\}S\{Q\}$ is a theorem in PL (i.e., derivable), the triple is actually true!

Example: we want

$$\{ x = 0 \} x := x + 1 \{ x = 1 \}$$

to be a theorem (since it was interpreted as true),

but

$$\{ x = 0 \} x := x + 1 \{ x = 0 \}$$

should not be a theorem (since it was interpreted as false)

Soundness: All theorems in PL are true

If we can use PL to prove some property of a program, then this property will hold for all executions of the program

Textual substitution

(Textual) substitution

 $P_{x\leftarrow e}$ means, all free occurrences of x in P are replaced by expression e.

Example

$$(x = 1)_{x \leftarrow (x+1)} \Leftrightarrow x + 1 = 1$$

$$(x + y = a)_{y \leftarrow (y+x)} \Leftrightarrow x + (y + x) = a$$

$$(y = a)_{x \leftarrow (x+y)} \Leftrightarrow y = a$$

Substitution propagates into formulas:

$$\begin{array}{lll} (\neg A)_{x \leftarrow e} & \Leftrightarrow & \neg (A_{x \leftarrow e}) \\ (A \land B)_{x \leftarrow e} & \Leftrightarrow & A_{x \leftarrow e} \land B_{x \leftarrow e} \\ (A \lor B)_{x \leftarrow e} & \Leftrightarrow & A_{x \leftarrow e} \lor B_{x \leftarrow e} \end{array}$$

$P_{x\leftarrow e}$

- Only free occurrences of x are substituted
- Variable occurrences may be *bound* by quantifiers, then that occurrence of the variable is not free (but bound)

Example (Substitution)

$$(\exists y : x + y > 0)_{x \leftarrow 1} \Leftrightarrow (\exists x : x + y > 0)_{x \leftarrow 1} \Leftrightarrow (\exists x : x + y > 0)_{y \leftarrow x} \Leftrightarrow (\exists x : x + y > 0)_{y \leftarrow x} \Leftrightarrow$$

Correspondingly for \forall

$P_{x\leftarrow e}$

- Only free occurrences of x are substituted
- Variable occurrences may be bound by quantifiers, then that occurrence of the variable is not free (but bound)

Example (Substitution)

$$(\exists y : x + y > 0)_{x \leftarrow 1} \Leftrightarrow \exists y : 1 + y > 0$$

$$(\exists x : x + y > 0)_{x \leftarrow 1} \Leftrightarrow$$

$$(\exists x : x + y > 0)_{y \leftarrow x} \Leftrightarrow$$

Correspondingly for ∀

$P_{x\leftarrow e}$

- Only free occurrences of x are substituted
- Variable occurrences may be *bound* by quantifiers, then that occurrence of the variable is not free (but bound)

Example (Substitution)

$$(\exists y : x + y > 0)_{x \leftarrow 1} \Leftrightarrow \exists y : 1 + y > 0$$

$$(\exists x : x + y > 0)_{x \leftarrow 1} \Leftrightarrow \exists x : x + y > 0$$

$$(\exists x : x + y > 0)_{y \leftarrow x} \Leftrightarrow$$

Correspondingly for \forall

$P_{x\leftarrow e}$

- Only free occurrences of x are substituted
- Variable occurrences may be bound by quantifiers, then that occurrence of the variable is not free (but bound)

Example (Substitution)

$$(\exists y : x + y > 0)_{x \leftarrow 1} \Leftrightarrow \exists y : 1 + y > 0$$

$$(\exists x : x + y > 0)_{x \leftarrow 1} \Leftrightarrow \exists x : x + y > 0$$

$$(\exists x : x + y > 0)_{y \leftarrow x} \Leftrightarrow \exists z : z + x > 0$$

Correspondingly for \forall

The assignment axiom – Motivation

Given by backward construction over the assignment:

 Given the postcondition to the assignment, we may derive the precondition!

What is the precondition?

$$\{?\} x := e \{x = 5\}$$

If the assignment x = e should terminate in a state where x has the value 5, the expression e must have the value 5 before the assignment:

$$\{ e = 5 \} \quad x := e \quad \{ x = 5 \}$$

 $\{ (x = 5)_{x \leftarrow e} \} \quad x := e \quad \{ x = 5 \}$

Axiom of assignment

"Backwards reasoning:" Given a postcondition, we may construct the precondition:

Axiom for the assignment statement

$$\{P_{x\leftarrow e}\}x := e\{P\}$$
 Assign

If the assignment x := e should lead to a state that satisfies P, the state before the assignment must satisfy P where x is replaced by e.

Proving an assignment

To prove the triple $\{P\}x := e\{Q\}$ in PL, we must show that the precondition P implies $Q_{x\leftarrow e}$

$$\frac{P \Rightarrow Q_{x \leftarrow e} \quad \left\{ Q_{x \leftarrow e} \right\} x := e \left\{ Q \right\}}{\left\{ P \right\} x := e \left\{ Q \right\}}$$

The blue implication is a logical proof obligation. In this course we only convince ourself that these are true (we do not prove them formally).

- $Q_{x\leftarrow e}$ is the largest set of states such that the assignment is guaranteed to terminate with Q
- largest set corresponds to weakest condition ⇒ weakest-precondition reasoning
- We must show that the set of states P is within this set

$$true \Rightarrow 1 = 1
\{ true \} x := 1 \{ x = 1 \}$$

$$x = 0 \Rightarrow x + 1 = 1
\{ x = 0 \} x := x + 1 \{ x = 1 \}$$

$$(x = a \land y = b) \Rightarrow x + y = a + b \land y = b
\{ x = a \land y = b \} x := x + y \{ x = a + b \land y = b \}$$

$$x = a \Rightarrow 0 * y + x = a
\{ x = a \} q := 0 \{ q * y + x = a \}$$

$$y > 0 \Rightarrow y \ge 0
\{ y > 0 \} x := y \{ x \ge 0 \}$$

Axiom of skip

```
The skip statement does nothing
```

Axiom:

```
\{\ P\ \}\ \mathsf{skip}\ \{\ P\ \}\quad \mathsf{Skip}
```

PL inference rules

$$\frac{\set{P}{S_1}\set{R}}{\set{P}{S_1};S_2\set{Q}} \operatorname{Seq}$$

$$\frac{\set{P \land B}{S}:S_2 \set{Q}}{\set{P \land \neg B} \Rightarrow Q} \operatorname{Cond}'$$

$$\frac{\set{P \land B}{S}:S \set{Q}}{\set{P} \text{ if } B \text{ then } S \set{Q}} \operatorname{Cond}'$$

$$\frac{\set{I \land B}:S \set{I}}{\set{I} \text{ while } B \text{ do } S \set{I \land \neg B}} \operatorname{While}$$

$$\frac{\set{P}:S \set{Q}}{\set{P'}:S \set{Q'}} \operatorname{Consequence}$$

- Blue: logical proof obligations
- the rule for while needs a loop invariant!
- for-loop: exercise 2.22!

Sequential composition and consequence

Backward construction over assignments:

$$\frac{x = y \Rightarrow 2 * x = 2 * y}{\{x = y\} x := x * 2 \{x = 2 * y\}} \qquad \{(x = y)_{y \leftarrow 2y} \} y := y * 2 \{x = y\}$$
$$\{x = y\} x := x * 2; y := y * 2 \{x = y\}$$

Sometimes we don't bother to write down the assignment axiom:

$$\frac{(q*y) + x = a \Rightarrow ((q+1)*y) + x - y = a}{\{ (q*y) + x = a \} x := x - y; \{ ((q+1)*y) + x = a \}}$$
$$\frac{\{ (q*y) + x = a \} x := x - y; q := q + 1 \{ (q*y) + x = a \}}{\{ (q*y) + x = a \}}$$

Logical variables

- Do not occur in program text
- Used only in assertions
- May be used to "freeze" initial values of variables
- May then talk about these values in the postcondition

Example

$$\{\; x= {\color{red} x_0}\;\}\; \textit{if} \, \big(x<0\big)\; \text{then}\; x:= -x\; \big\{\; x\geq 0 \, \land \big(x= {\color{red} x_0} \, \lor \, x= -{\color{red} x_0}\big)\;\big\}$$

where $(x = x_0 \lor x = -x_0)$ states that

- the final value of x equals the initial value, or
- the final value of x is the negation of the initial value

Example: if statement

Verification of:

$$\{\; x=x_0 \;\} \; \text{ if } \big(x<0\big) \; \text{then} \; x:=-x \; \big\{\; x\geq 0 \land \big(x=x_0 \lor x=-x_0\big) \; \big\}$$

$$\frac{\{P \land B\} \ S \ \{Q\} \qquad (P \land \neg B) \Rightarrow Q}{\{P\} \ \text{if} \ B \ \text{then} \ S \ \{Q\}} \ \text{Cond'}$$

• { $P \land B$ } S { Q }: { $x = x_0 \land x < 0$ } x := -x { $x \ge 0 \land (x = x_0 \lor x = -x_0)$ } Backward construction (assignment axiom) gives the implication:

$$x = x_0 \land x < 0 \Rightarrow (-x \ge 0 \land (-x = x_0 \lor -x = -x_0))$$

 $P \land \neg B \Rightarrow Q:$ $x = x_0 \land x \ge 0 \Rightarrow (x \ge 0 \land (x = x_0 \lor x = -x_0))$

Example: if statement

Verification of:

$$\{\; x=x_0 \;\} \; \text{ if } \big(x<0\big) \; \text{then} \; x:=-x \; \big\{\; x\geq 0 \land \big(x=x_0 \lor x=-x_0\big) \; \big\}$$

$$\frac{\{P \land B\} \ S \ \{Q\} \qquad (P \land \neg B) \Rightarrow Q}{\{P\} \ \text{if} \ B \ \text{then} \ S \ \{Q\}} \ \text{Cond'}$$

• { $P \land B$ } S { Q }: { $x = x_0 \land x < 0$ } x := -x { $x \ge 0 \land (x = x_0 \lor x = -x_0)$ } Backward construction (assignment axiom) gives the implication:

$$x = x_0 \land x < 0 \Rightarrow (-x \ge 0 \land (-x = x_0 \lor -x = -x_0))$$

• $P \land \neg B \Rightarrow Q$: $x = x_0 \land x \ge 0 \Rightarrow (x \ge 0 \land (x = x_0 \lor x = -x_0))$

INF4140 - Models of concurrency Program Analysis, lecture 6

Høsten 2014

3.10.2014

Program Analysis

Program Logic (PL)

- PL lets us express and prove properties about programs
- Formulas are on the form

"triple"

- S: program statement(s)
- P and Q: assertions over program states
- P: Pre-condition
- Q: Post-condition

If we can use PL to prove some property of a program, then this property will hold for all executions of the program

PL rules from last week

$$\frac{\set{P} S_1 \set{R} \qquad \set{R} S_2 \set{Q}}{\set{P} S_1; S_2 \set{Q}} \operatorname{Seq}$$

$$\frac{\set{P \land B} S \set{Q} \qquad P \land \neg B \Rightarrow Q}{\set{P} \text{ if } B \text{ then } S \set{Q}} \operatorname{Cond}'$$

$$\frac{\set{I \land B} S \set{I}}{\set{I} \text{ while } B \text{ do } S \set{I \land \neg B}} \operatorname{While}$$

$$\frac{\set{P} S \set{Q} \qquad P' \Rightarrow P \qquad Q \Rightarrow Q'}{\set{P'} S \set{Q'}} \operatorname{Consequence}$$

While rule

- Cannot control the execution in the same manner as for if statements
 - Cannot tell from the code how many times the loop body will be executed

$$\{ y \ge 0 \} \text{ while } (y > 0) \ y := y - 1$$

- Cannot speak about the state after the first, second, third iteration
- Solution: Find an assertion / that is maintained by the loop body
 - Loop invariant: express a property preserved by the loop
- Often hard to find suitable loop invariants
 - This course is *not* an exercise in finding complicated invariants

While rule

$$\frac{\{I \land B\} S \{I\}}{\{I\} \text{ while } B \text{ do } S \{I \land \neg B\}} \text{ While}$$

Can use this rule to reason about the more general case:

$$\{P\}$$
 while $B \text{ do } S \{Q\}$

where

- P need not be the loop invariant
- Q need not match $(I \land \neg B)$ syntactically

Combine While-rule with Consequence-rule to prove:

- Entry: $P \Rightarrow I$
- Loop: { *I* ∧ *B* } *S* { *I* }
- Exit: $I \wedge \neg B \Rightarrow Q$

While rule: example

$$\{\ 0 \le n\ \}\ k := 0;\ \{\ k \le n\ \}\ \ {\rm while}\ \ (k < n)\ k := k+1;\ \{\ k = n\ \}$$

Composition rule splits a proof in two: assignment and loop. Let $k \le n$ be the loop invariant

- Entry: $k \le n$ follows from itself
- Loop:

$$\frac{k < n \Rightarrow k + 1 \le n}{\{ k \le n \land k < n \} \ k := k + 1 \{ k \le n \}}$$

• Exit: $(k \le n \land \neg(k < n)) \Rightarrow k = n$

Await statement

Rule for await

$$\frac{\{P \land B\} S \{Q\}}{\{P\} \langle await(B) S \rangle \{Q\}} Await$$

Remember: we are reasoning about safety properties

- Termination is assumed/ignored
- the rule does not speak about waiting or progress

Assume two statements S_1 and S_2 such that:

$$\{P_1\}\langle S_1\rangle \{Q_1\} \text{ and } \{P_2\}\langle S_2\rangle \{Q_2\}$$

Note: to avoid further complications right now: S_i 's are enclosed into " \langle atomic brackets \rangle ".

First attempt for a co...oc rule in PL:

Example (Problem with this rule)

$$\frac{\{\; x=0\;\}\; \langle x:=x+1\rangle\; \{\; x=1\;\} \qquad \{\; x=0\;\}\; \langle x:=x+2\rangle\; \{\; x=2\;\}}{\{\; x=0\;\}\;\; \operatorname{co}\langle x:=x+1\rangle\; \|\; \langle x=x+2\rangle\; \operatorname{oc}\; \{\; x=1\land x=2\;\}}$$

but this conclusion is not true: the postcondition should be $extit{x}=3$!

Assume two statements S_1 and S_2 such that:

$$\{P_1\}\langle S_1\rangle$$
 $\{Q_1\}$ and $\{P_2\}\langle S_2\rangle$ $\{Q_2\}$

Note: to avoid further complications right now: S_i 's are enclosed into " \langle atomic brackets \rangle ".

First attempt for a co...oc rule in PL:

$$\frac{\Set{P_1} \lang{S_1} \Set{Q_1}}{\Set{P_1 \land P_2} \texttt{co} \lang{S_1} \parallel \lang{S_2} \texttt{oc} \Set{Q_1 \land Q_2}} \mathsf{Par}$$

Example (Problem with this rule)

$$\frac{\{\; x=0\;\}\; \langle x:=x+1\rangle\; \{\; x=1\;\} \qquad \{\; x=0\;\}\; \langle x:=x+2\rangle\; \{\; x=2\;\}}{\{\; x=0\;\}\;\; \operatorname{co}\langle x:=x+1\rangle\; \|\; \langle x=x+2\rangle\; \operatorname{oc}\; \{\; x=1\land x=2\;\}}$$

but this conclusion is not true: the postcondition should be x=3

Assume two statements S_1 and S_2 such that:

$$\{P_1\}\langle S_1\rangle \{Q_1\} \text{ and } \{P_2\}\langle S_2\rangle \{Q_2\}$$

Note: to avoid further complications right now: S_i 's are enclosed into " $\langle atomic brackets \rangle$ ".

First attempt for a co...oc rule in PL:

$$\frac{\Set{P_1} \langle S_1 \rangle \Set{Q_1}}{\Set{P_1 \wedge P_2} \operatorname{co}\langle S_1 \rangle \parallel \langle S_2 \rangle \operatorname{ct} \Set{Q_1}} \operatorname{Par}$$

Example (Problem with this rule)

$$\frac{\{\; x=0\;\}\; \langle x:=x+1\rangle\; \{\; x=1\;\} \qquad \{\; x=0\;\}\; \langle x:=x+2\rangle\; \{\; x=2\;\}}{\{\; x=0\;\}\;\; \operatorname{co}\langle x:=x+1\rangle\; \|\; \langle x=x+2\rangle\; \operatorname{oc}\; \{\; x=1\;\wedge\; x=2\;\}}$$

but this conclusion is not true: the postcondition should be x = 3!

$$S_1 \quad \{ \ x = 0 \ \} \ \langle x := x + 1 \rangle \ \{ \ x = 1 \ \}$$
 $S_2 \quad \{ \ x = 0 \ \} \ \langle x := x + 2 \rangle \ \{ \ x = 2 \ \}$

- ullet execution of S_2 interferes with pre- and postconditions of S_1
 - The assertion x = 0 need not hold when S_1 starts execution
- ullet execution of S_1 interferes with pre- and postconditions of S_2
 - The assertion x = 0 need not hold when S_2 starts execution

Solution: weaken the assertions to account for the other process:

$$S_1 \quad \{ x = 0 \lor x = 2 \} \ \langle x := x + 1 \rangle \ \{ x = 1 \lor x = 3 \}$$

 $S_2 \quad \{ x = 0 \lor x = 1 \} \ \langle x := x + 2 \rangle \ \{ x = 2 \lor x = 3 \}$

$$S_1 \quad \{ \ x = 0 \ \} \ \langle x := x + 1 \rangle \ \{ \ x = 1 \ \}$$
 $S_2 \quad \{ \ x = 0 \ \} \ \langle x := x + 2 \rangle \ \{ \ x = 2 \ \}$

- ullet execution of S_2 interferes with pre- and postconditions of S_1
 - The assertion x = 0 need not hold when S_1 starts execution
- ullet execution of S_1 interferes with pre- and postconditions of S_2
 - The assertion x = 0 need not hold when S_2 starts execution

Solution: weaken the assertions to account for the other process:

$$S_1 \quad \{ \ x = 0 \lor x = 2 \ \} \ \langle x := x + 1 \rangle \ \{ \ x = 1 \lor x = 3 \ \}$$

$$S_2 \{ x = 0 \lor x = 1 \} \langle x := x + 2 \rangle \{ x = 2 \lor x = 3 \}$$

Now we can try to apply the rule:

where:

PRE :
$$(x = 0 \lor x = 2) \land (x = 0 \lor x = 1)$$

POST : $(x = 1 \lor x = 3) \land (x = 2 \lor x = 3)$

Now we can try to apply the rule:

where:

PRE :
$$(x = 0 \lor x = 2) \land (x = 0 \lor x = 1)$$

POST : $(x = 1 \lor x = 3) \land (x = 2 \lor x = 3)$

which gives:

$$\{ x = 0 \} \text{ co } \| x = x + 1 \| \langle x := x + 2 \rangle \text{ oc } \{ x = 3 \}$$

Assume $\{P_i\}$ S_i $\{Q_i\}$ for all S_1, \ldots, S_n

$$\frac{\{\ P_i\ \}\ S_i\ \{\ Q_i\ \}\quad \text{are interference free}}{\{\ P_1\wedge\ldots\wedge P_n\ \}\ \operatorname{co} S_1\parallel\ldots\parallel S_n\operatorname{oc}\ \{\ Q_1\wedge\ldots\wedge Q_n\ \}}\operatorname{\mathsf{Cooc}}$$

Interference freedom

A process interferes with (the specification of) another process, if its execution changes the values of the assertions^a of the other process.

- assertions inside awaits: not endagered
- critical assertions or critical conditions: assertions outside await statement bodies.²⁸

321 / 578

^aOnly "critical assertions" considered

Interference freedom

Interference freedom

- S: statement some process, with pre-condition pre(S)
- C: critical assertion in another process
- *S* does not interfere with *C*, if

$$\{ C \land pre(S) \} S \{ C \}$$

is derivable in PL (= theorem).

"C is invariant under the execution of the other process"

$$\frac{\{P_1\} S_1 \{Q_1\} \qquad \{P_2\} S_2 \{Q_2\}}{\{P_1 \land P_2\} \cos S_1 \parallel S_2 \cos \{Q_1 \land Q_2\}}$$

Four interference freedom requirements:

$$S_1: \{ x = 0 \} < x := x + 1; > \{ x = 1 \}$$

 $S_2: \{ x = 0 \} < x := x + 2; > \{ x = 2 \}$

Here we have interference, for instance the precondition of S_1 is not maintained by execution of S_2 :

$$\{(x=0) \land (x=0)\} x := x+2 \{x=0\}$$

is not true

However, after weakening:

$$S_1: \{x = 0 \lor x = 2 \} \langle x := x + 1 \rangle \{x = 1 \lor x = 3 \}$$

$$S_2: \{x = 0 \lor x = 1 \} \langle x := x + 2 \rangle \{x = 2 \lor x = 3 \}$$

$$\{(x = 0 \lor x = 2) \land (x = 0 \lor x = 1) \} x := x + 2 \{x = 0 \lor x = 2 \}$$
(Correspondingly for the other three critical conditions)

(Correspondingly for the other times circled conditions)

Avoiding interference: Disjoint variables

- V set: global variables referred (i.e. read or written) to by a process
- W set: global variables written to by a process
- Reference set: global variables in critical assertions/conditions of one process

 S_1 and S_2 : in 2 different processes. No interference, if:

- W set of S_1 is disjoint from reference set of S_2
- W set of S_2 is disjoint from reference set of S_1

Alas: variables in a critical condition of one process will often be among the written variables of another

Avoiding interference: Global invariants

global invariants

- Some conditions. that only refer to global (shared) variables
- Holds initially
- Preserved by all assignments

We avoid interference if critical conditions are on the form $\{I \wedge L\}$ where:

- I is a global invariant
- L only refers to local variables of the considered process

Avoiding interference: Synchronization

- Hide critical conditions
- MUTEX to critical sections

$$co...; S; ... \parallel ...; S_1; \{ C \} S_2; ... oc$$

S might interfere with C Hide the critical condition by a critical region:

$$co...; S; ... \parallel ...; \langle S_1; \{ C \} S_2 \rangle; ... oc$$

Example: Producer/ consumer synchronization

Let process Producer deliver data to a Consumer process

```
PC: c \le p \le c+1 \land (p=c+1) \Rightarrow (buf = a[p-1])
Let PC be a global invariant of the program:
```

```
int buf, p := 0; c := 0;
2
3
   process Producer {
                                       process Consumer {
     int a[N];...
                                       int b[N];...
      while (p < N) {
                                       while (c < N) {
6
       < await (p = c); >
                                       < await (p > c); >
8
       buf := a[p];
                                         b[c] := buf;
                                            c := c+1;
         p := p+1;
10
11
```

Let process Producer deliver data to a Consumer process

$$PC: c \leq p \leq c+1 \land (p=c+1) \Rightarrow (buf = a[p-1])$$

Let *PC* be a *global invariant* of the program:

```
int buf, p := 0; c := 0;
2
3
   process Producer {
                                      process Consumer {
     int a[N];...
                                      int b[N];...
     while (p < N) {
                                       while (c < N) {
6
       < await (p = c); >
                                       < await (p > c); >
8
       buf := a[p];
                                        b[c] := buf;
                                            c := c+1;
         p := p+1;
10
11
```

```
Loop invariant of Producer:
```

```
I_P: PC \land p < n
      process Producer dir0o
        int a[n]:
        \{ I_P dir \}
                                       // entering loop
        while (p < n) dir0o
           < await (p == c); > { l_P \land p < n \land p = c }
           buf = a[p];

Example: Producer/Consumer

The final state of the program satisfies:

$$PC \land p = n \land c = n \land b[0:c-1] = a[0:c-1]$$

which ensures that all elements in a are received and occur in the same order in b

Interference freedom is ensured by the global invariant and await-statements

If we combine the two assertions after the await statements, we get:

$$I_P \wedge p < n \wedge p = c \wedge I_C \wedge c < n \wedge p > c$$

which gives false!

At any time, only one process can be after the await statement!

Example: Producer/Consumer

The final state of the program satisfies:

$$PC \land p = n \land c = n \land b[0 : c - 1] = a[0 : c - 1]$$

which ensures that all elements in a are received and occur in the same order in b

Interference freedom is ensured by the global invariant and await-statements

If we combine the two assertions after the await statements, we get:

$$I_P \wedge p < n \wedge p = c \wedge I_C \wedge c < n \wedge p > c$$

which gives false!

At any time, only one process can be after the await statement!

Monitor invariant

```
monitor name dir0o
monitor variables  # shared global variable
initialization  # for the monitor's procedures
procedures
dir
```

- A monitor invariant (/): used to describe the monitor's inner state
- Express relationship between monitor variables
- Maintained by execution of procedures:
 - Must hold after initialization
 - Must hold when a procedure terminates
 - •
 - •
- Should be as strong as possible!

Monitor invariant

```
monitor name dir0o
monitor variables  # shared global variable
initialization  # for the monitor's procedures
procedures
dir
```

- A monitor invariant (/): used to describe the monitor's inner state
- Express relationship between monitor variables
- Maintained by execution of procedures:
 - Must hold after initialization
 - Must hold when a procedure terminates
 - Must hold when we suspend execution due to a call to wait
 - Can assume that the invariant holds after wait and when a procedure starts
- Should be as strong as possible!

Assume that the monitor invariant I and predicate P doe not mention cv. Then we can set up the following axioms:

```
\{\ I\ \}\ wait(cv)\ \{\ I\ \}
\{\ P\ \}\ signal(cv)\ \{\ P\ \} for arbitrary P
\{\ P\ \}\ signal\_all(cv)\ \{\ P\ \} for arbitrary P
```

```
I: (nr = 0 \lor nw = 0) \land nw \le 1
procedure request_read() {
    wait(oktoread);
    \{ 1 \land nw = 0 \}
    nr = nr + 1;
```

```
I: (nr = 0 \lor nw = 0) \land nw \le 1
procedure request_read() {
       { / }
       while (nw > 0) { \langle 1 \wedge nw \rangle \rangle
             { / } wait(oktoread); { / }
       \{ 1 \land nw = 0 \}
       nr = nr + 1;
       { / }
```

```
I: (nr = 0 \lor nw = 0) \land nw \le 1
procedure request_read() {
       { / }
       while (nw > 0) { \langle 1 \wedge nw \rangle \rangle
             { / } wait(oktoread); { / }
       \{ 1 \land nw = 0 \}
       nr = nr + 1;
       { / }
```

```
I: (nr = 0 \lor nw = 0) \land nw \le 1
  procedure request_read() {
          { / }
          while (nw > 0) { \{ I \land nw > 0 \}
                { / } wait(oktoread); { / }
          \{ 1 \land nw = 0 \}
          nr = nr + 1;
          { / }
(I \wedge nw > 0) \Rightarrow I
```

```
I: (nr = 0 \lor nw = 0) \land nw \le 1
   procedure request_read() {
           { / }
           while (nw > 0) { / nw > 0 }
                  { / } wait(oktoread); { / }
           \{ I \land nw = 0 \}
           \{I_{nr\leftarrow nr+1}\}
           nr = nr + 1;
           { / }
(I \wedge nw > 0) \Rightarrow I
(I \wedge nw = 0) \Rightarrow I_{nr \leftarrow nr+1}
```

Assume that the invariant can mention the number of processes in the queue to a condition variable.

- Let #cv be the number of proc's waiting in the queue to cv.
- The test empty(cv) thus corresponds to #cv = 0

wait(cv) is *modelled* as an extension of the queue followed by processor release:

$$wait(cv): \{7\} \# cv = \# cv + 1; \{I\} "sleep" \{I\} \}$$

$$wait(cv) : \{I_{\#cv \leftarrow \#cv+1}; \#cv := \#cv + 1; \{I\} \text{ "sleep"}\{I\} \}$$

Assume that the invariant can mention the number of processes in the queue to a condition variable.

- Let #cv be the number of proc's waiting in the queue to cv.
- The test empty(cv) thus corresponds to #cv = 0

wait(cv) is *modelled* as an extension of the queue followed by processor release:

$$wait(cv): \{7\} \#cv = \#cv + 1; \{I\} \text{ "sleep"}\{I\}$$

$$wait(cv) : \{I_{\#cv \leftarrow \#cv+1}; \#cv := \#cv + 1; \{I\} \text{ "sleep"}\{I\} \}$$

Assume that the invariant can mention the number of processes in the queue to a condition variable.

- Let #cv be the number of proc's waiting in the queue to cv.
- The test empty(cv) thus corresponds to #cv = 0

wait(cv) is *modelled* as an extension of the queue followed by processor release:

$$wait(cv): \{7\} \#cv = \#cv + 1; \{1\} \text{ "sleep"}\{1\}$$

$$wait(cv) : \{I_{\#cv \leftarrow \#cv+1}; \#cv := \#cv + 1; \{I\} \text{ "sleep"}\{I\} \}$$

Assume that the invariant can mention the number of processes in the queue to a condition variable.

- Let #cv be the number of proc's waiting in the queue to cv.
- The test empty(cv) thus corresponds to #cv = 0

wait(cv) is *modelled* as an extension of the queue followed by processor release:

$$wait(cv): \{?\} \#cv = \#cv + 1; \{I\} \text{ "sleep"}\{I\}$$

$$wait(cv): \{I_{\#cv \leftarrow \#cv+1}; \#cv := \#cv + 1; \{I\} \text{ "sleep"}\{I\} \}$$

Assume that the invariant can mention the number of processes in the queue to a condition variable.

- Let #cv be the number of proc's waiting in the queue to cv.
- The test empty(cv) thus corresponds to #cv = 0

wait(cv) is *modelled* as an extension of the queue followed by processor release:

$$wait(cv) : \{?\} \#cv = \#cv + 1; \{I\} \text{ "sleep"}\{I\}$$

$$wait(cv): \{I_{\#cv \leftarrow \#cv+1}; \#cv := \#cv + 1; \{I\} \text{ "sleep"}\{I\} \}$$

signal(cv) can be modelled as a reduction of the queue, if the queue is not empty:

$$signal(cv): \{?\} if (\#cv \neq 0) \#cv := \#cv - 1 \{P\}$$

signal(cv):
$$\{((\#cv = 0) \Rightarrow P) \land ((\#cv \neq 0) \Rightarrow P_{\#cv \leftarrow \#cv - 1})\}$$

if $(\#cv \neq 0) \#cv := \#cv - 1$
 $\{P\}$

•
$$signal_all(cv)$$
: $P_{\#cv=0}$ $\#cv:=0$ P

signal(cv) can be modelled as a reduction of the queue, if the queue is not empty:

$$signal(cv): \{?\} if (\#cv \neq 0) \#cv := \#cv - 1 \{P\}$$

signal(cv):
$$\{((\#cv = 0) \Rightarrow P) \land ((\#cv \neq 0) \Rightarrow P_{\#cv \leftarrow \#cv - 1})\}$$

if $(\#cv \neq 0) \#cv := \#cv - 1$
 $\{P\}$

• $signal_all(cv)$: $|P_{\#cv=0}| \#cv := 0 |P|$

signal(cv) can be modelled as a reduction of the queue, if the queue is not empty:

$$signal(cv): \{?\} if (\#cv \neq 0) \#cv := \#cv - 1 \{P\}$$

$$signal(cv): \{((\#cv=0)\Rightarrow P) \land ((\#cv\neq 0)\Rightarrow P_{\#cv\leftarrow\#cv-1})\}$$

$$if (\#cv\neq 0) \#cv := \#cv - 1$$

$$\{P\}$$

• $signal_all(cv)$: $P_{\#cv=0}$ #cv := 0 P

signal(cv) can be modelled as a reduction of the queue, if the queue is not empty:

$$signal(cv): \{?\} if (\#cv \neq 0) \#cv := \#cv - 1 \{P\}$$

signal(cv):
$$\{((\#cv = 0) \Rightarrow P) \land ((\#cv \neq 0) \Rightarrow P_{\#cv \leftarrow \#cv - 1})\}$$

if $(\#cv \neq 0) \#cv := \#cv - 1$
 $\{P\}$

• $signal_all(cv)$: { $P_{\#cv=0}$ } #cv := 0 { P}

signal(cv) can be modelled as a reduction of the queue, if the queue is not empty:

$$signal(cv): \{?\} if (\#cv \neq 0) \#cv := \#cv - 1 \{P\}$$

$$signal(cv): \begin{cases} ((\#cv = 0) \Rightarrow P) \land ((\#cv \neq 0) \Rightarrow P_{\#cv \leftarrow \#cv - 1}) \\ if (\#cv \neq 0) \#cv := \#cv - 1 \\ \{P\} \end{cases}$$

• $signal_all(cv)$: { $P_{\#cv\leftarrow 0}$ } #cv := 0 { P }

Axioms for Signal and Continue (3)

signal(cv) can be modelled as a reduction of the queue, if the queue is not empty:

$$signal(cv): \{?\} if (\#cv \neq 0) \#cv := \#cv - 1 \{P\}$$

$$\begin{aligned} \text{signal}(\textit{cv}): & \; \{((\#\textit{cv} = 0) \Rightarrow \textit{P}) \land ((\#\textit{cv} \neq 0) \Rightarrow \textit{P}_{\#\textit{cv} \leftarrow \#\textit{cv} - 1}\} \\ & \; \textit{if} \; (\#\textit{cv} \neq 0) \; \#\textit{cv} := \#\textit{cv} - 1 \\ & \; \{\textit{P}\} \end{aligned}$$

• $signal_all(cv)$: { $P_{\#cv \leftarrow 0}$ } #cv := 0 { P}

Axioms for Signal and Continue (3)

signal(cv) can be modelled as a reduction of the queue, if the queue is not empty:

$$signal(cv): \{?\} if (\#cv \neq 0) \#cv := \#cv - 1 \{P\}$$

$$\begin{aligned} \text{signal}(\textit{cv}): & \; \{((\#\textit{cv} = 0) \Rightarrow \textit{P}) \land ((\#\textit{cv} \neq 0) \Rightarrow \textit{P}_{\#\textit{cv} \leftarrow \#\textit{cv} - 1}\} \\ & \; \textit{if} \; (\#\textit{cv} \neq 0) \; \#\textit{cv} := \#\textit{cv} - 1 \\ & \; \{\textit{P}\} \end{aligned}$$

• $signal_all(cv)$: { $P_{\#cv \leftarrow 0}$ } #cv := 0 {P}

Axioms for Signal and Continue (4)

Together this gives:

Axioms for monitor communication

```
{ I_{\#cv \leftarrow (\#cv+1)} } wait(cv) { I } wait
{ ((\#cv=0)\Rightarrow P) \land ((\#cv\neq 0)\Rightarrow P_{\#cv \leftarrow (\#cv-1)}) } signal(cv) { P }
{ P_{\#cv \leftarrow 0} } signal_all(cv) { P } SignalAll
```

If we know that $\#cv \neq 0$ whenever we signal, then the axiom for signal(cv) be simplified to:

$$\{P_{\#cv \leftarrow (\#cv-1)}\}$$
signal (cv) $\{P\}$

Note! #cv is not allowed in statements!, Only used for reasoning

\{I_{s \leftarrow (s+1)} \mid s := s+1; \{I\}
else \{I \land \#pos \ne 0\}
\{I_{\#pos \leftarrow (\#pos-1)}\} \text{ signal(pos); } \{I\}
dir
```

```
I: s \ge 0 \land (s > 0 \Rightarrow \#pos = 0) procedure Vsem() dir0o \{I\} if empty(pos) \{I \land \#pos = 0\} \{I_{s \leftarrow (s+1)}\}s := s+1; \{I\} else \{I \land \#pos \ne 0\} \{I_{\#pos \leftarrow (\#pos-1)}\} \text{ signal(pos); }\{I\} dir
```

```
\begin{split} I: & s \geq 0 \land (s > 0 \Rightarrow \#pos = 0) \\ \text{procedure Vsem() dir0o} \\ \{I\} & \text{if empty(pos)} & \{I \land \#pos = 0\} \\ & \{I_{s \leftarrow (s+1)}\}s := s+1; & \{I\} \\ & \text{else} & \{I \land \#pos \neq 0\} \\ & \{I_{\#pos \leftarrow (\#pos-1)}\} \text{ signal(pos); } \{I\} \\ \text{dir} \end{split}
```

$$I: s \ge 0 \land (s > 0 \Rightarrow \#pos = 0)$$

As above, this gives two proof obligations: If-branch:

$$\begin{array}{ll} (I \land \#pos = 0) & \Rightarrow & I_{s \leftarrow (s+1)} \\ (s \geq 0 \land \#pos = 0) & \Rightarrow & s+1 \geq 0 \land (s+1>0 \Rightarrow \#pos = 0) \\ (s \geq 0 \land \#pos = 0) & \Rightarrow & s+1 \geq 0 \land \#pos = 0 \end{array}$$

Else branch:

$$\begin{array}{ll} (I \land \#pos \neq 0) & \Rightarrow & I_{\#pos \leftarrow (\#pos - 1)} \\ (s = 0 \land \#pos \neq 0) & \Rightarrow & s \geq 0 \land (s > 0 \Rightarrow \#pos - 1 = 0) \\ s = 0 & \Rightarrow & s \geq 0 \end{array}$$

$$I: s \ge 0 \land (s > 0 \Rightarrow \#pos = 0)$$

As above, this gives two proof obligations: If-branch:

$$\begin{array}{ll} (I \land \#pos = 0) & \Rightarrow & I_{s \leftarrow (s+1)} \\ (s \geq 0 \land \#pos = 0) & \Rightarrow & s+1 \geq 0 \land (s+1>0 \Rightarrow \#pos = 0) \\ (s \geq 0 \land \#pos = 0) & \Rightarrow & s+1 \geq 0 \land \#pos = 0 \end{array}$$

Else branch:

$$\begin{array}{ll} (I \land \#pos \neq 0) & \Rightarrow & I_{\#pos \leftarrow (\#pos - 1)} \\ (s = 0 \land \#pos \neq 0) & \Rightarrow & s \geq 0 \land (s > 0 \Rightarrow \#pos - 1 = 0) \\ s = 0 & \Rightarrow & s \geq 0 \end{array}$$

Java concurrency

INF4140 - Models of concurrency Java concurrency, lecture 7

Høsten 2014

10. 10. 2014

Outline

- 1. Monitors: review
- 2. Threads in Java:
 - Thread classes and Runnable interfaces
 - Interference and Java threads
 - Synchronized blocks and methods: (atomic regions and monitors)
- 3. Example: The ornamental garden
- Thread communication & condition synchronization (wait and signal/notify)
- 5. Example: Mutual exclusion
- 6. Example: Readers/writers

Short recap of monitors

- monitor encapsulates data, which can only be observed and modified by the monitor's procedures
 - Contains variables that describe the state
 - variables can be accessed/changed only through the available procedures
- Implicit mutex: Only a procedure may be active at a time.
 - 2 procedures in the same monitor: never executed concurrently
- Condition synchronization: block a process until a particular condition holds, achieved through condition variables.

Signaling disciplines

- Signal and wait (SW): the signaller waits, and the signalled process gets to execute immediately
- Signal and continue (SC): the signaller continues, and the signalled process executes later

From Wikipedia:29

" ... Java is a general-purpose, concurrent, class-based, object-oriented language ... "

²⁹But it's correct nonetheless . . .

Threads in Java

A thread in Java

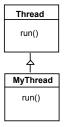

- unit of concurrency³⁰
- identity, accessible via static method Thread.CurrentThread()³¹
- has its own stack / execution context
- access to shared state
- shared mutable state: heap structured into objects
 - privacy restrictions possible
 - what are private fields?
- may be created (and deleted) dynamically

 $^{^{30}}$ as such, roughly corresponding to the concept of "processes" from previous lecctures.

³¹What's the difference to this?

Thread class

The Thread class executes instructions from its method run(). The actual code executed depends on the implementation provided for run() in a derived class.

```
class MyThread extends Thread {
  public void run() {
    //.....
}

// Creating a thread object:
Thread a = new MyThread();
  a.start();
```

Runnable interface

As Java does not support multiple inheritance, we often implement the run() method in a class not derived from Thread but from the interface Runnable.

```
Runnable | Thread |

run() | public interface Runnable { | public abstract void run(); | } |

MyRun | class MyRun implements Runnable { | public void run() { | //..... | } | }
```

```
// Creating a thread object:
Runnable b = new MyRun();
new Thread(b).start();
```

Threads in Java

steps to create a thread in Java and get it running:

- 1. Define class that
 - extends the Java Thread class or
 - implements the Runnable interface
- 2. define run method inside the new class³²
- 3. create an instance of the new class.
- 4. *start* the thread.

³²overriding, late-binding.

```
class Store {
    private int data = 0;
    public void update() { data++; }
}

// in a method:
Store s = new Store(); // the threads below have access to s
t1 = new FooThread(s); t1.start();
t2 = new FooThread(s); t2.start();
```

t1 and t2 execute s.update() concurrently!
Interference between t1 and t2 ⇒ may lose updates to data.

Synchronization

avoid interference ⇒ threads "synchronize" access to shared data

- 1. One unique lock for each object o.
- 2. mutex: at most one thread t can lock o at any time.³³
- 3. 2 "flavors"

```
"synchronized block"
```

```
synchronized (o) { B }
```

synchronized method

whole method body of m "protected" a:

```
synchronized Type m(...) { ... }
```

^aassuming that other methods play according to the rules as well etc.

³³but: in a re-entrant manner!

Protecting the initialization

Solution to earlier problem: lock the Store objects before executing problematic method:

```
class Store {
  private int data = 0;

public void update() {
  synchronized (this) { data++; }
  }
}
```

or

```
class Store {
  private int data = 0;

public synchronized void update() {data++; }

public synchronized void update() {data++; }

// inside a method:
Store s = new Store();
```

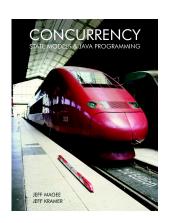

Java Examples

Book:

Concurrency: State Models & Java Programs, 2nd Edition

Jeff Magee & Jeff Kramer

Wiley

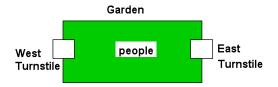

Examples in Java:

http://www.doc.ic.ac.uk/~jnm/book/

Ornamental garden problem

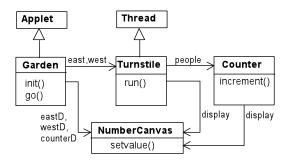

- people enter an ornamental garden through either of 2 turnstiles.
- problem: the number of people present at any time.

The concurrent program consists of:

- 2 threads
- shared counter object

Ornamental garden problem: Class diagram

The Turnstile thread simulates the periodic arrival of a visitor to the garden every second by sleeping for a second and then invoking the increment() method of the counter object.

```
class Counter {
3
       int value = 0;
       NumberCanvas display;
5
6
7
       Counter(NumberCanvas n) {
         display = n;
8
         display.setvalue(value);
9
10
11
12
        void increment() {
          int temp = value;
                                           // read[v]
13
          Simulate . HWinterrupt ();
14
          value = temp + 1;
                                           // write[v+1]
15
               display.setvalue(value);
16
17
18
```

2

3

5

6

7 8

9 10

11 12

13

14

15

16

17 18

```
class Turnstile extends Thread {
 NumberCanvas display; // interface
 Counter people; // shared data
 Turnstile (NumberCanvas n, Counter c) { // constructor
     display = n;
     people = c;
 public void run() {
     try {
       display.setvalue(0);
       for (int i = 1; i \le Garden.MAX; i++) {
        Thread.sleep (500); // 0.5 second
         display.setvalue(i);
         people.increment(); // increment the counter
     } catch (InterruptedException e) { }
```

Ornamental Garden Program

The Counter object and Turnstile threads are created by the go() method of the Garden applet:

```
private void go() {
    counter = new Counter(counterD);
    west = new Turnstile(westD, counter);
    east = new Turnstile(eastD, counter);
    west.start();
    east.start();
}
```

Ornamental Garden Program: DEMO

DEMO

After the East and West turnstile threads have each incremented its counter 20 times, the garden people counter is not the sum of the counts displayed. Counter increments have been lost. Why?

Avoid interference by synchronization

Mutual Exclusion: The Ornamental Garden - DEMO

DEMO

Monitors

- each object
 - has attached to it a unique lock
 - and thus: can act as monitor
- 3 important monitor operations³⁴
 - o.wait(): release lock on o, enter o's wait queue and wait
 - o.notify(): wake up one thread in o's wait queue
 - o.notifyAll(): wake up all threads in o's wait queue
- ullet executable by a thread "inside" the monitor represented by o
- executing thread must hold the lock of o/ executed within synchronized portions of code
- typical use: this.wait() etc.
- note: notify does not operate on a thread-identity³⁵

```
Thread t = new MyThread();

...
t.notify();; // mostly to be nonsense
```

³⁴there are more

³⁵technically, a thread identity is represented by a "thread object" though.

Condition synchronization, scheduling, and signaling

- quite simple/weak form of monitors in Java
- only one (implicit) condition variable per object: availability of the lock. threads that wait on o (o.wait()) are in this queue
- no built-in support for general-purpose condition variables.
- ordering of wait "queue": implementation-dependent (usually FIFO)
- signaling discipline: S & C
- awakened thread: no advantage in competing for the lock to o.
- note: monitor-protection not enforced
 - ullet private field modifier eq instance private
 - not all methods need to be synchronized³⁶
 - besides that: there's re-entrance!

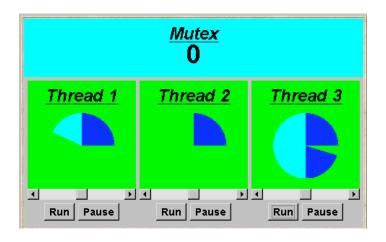

³⁶remember: find of oblig-1.

```
// down() = P operation
     //up() = V operation
3
4
   public class Semaphore {
5
        private int value;
6
        public Semaphore (int initial) {
7
            value = initial:
8
9
10
        synchronized public void up() {
11
            ++value:
12
            notifyAll();}
13
14
        synchronized public void down() throws InterruptedException {
15
            while (value==0) wait(); // the well-known while-cond-wait
16
            - -value;}
17
18
```

 cf. also java.util.concurrency.Semaphore (acquire/release + more methods)

Mutual exclusion with sempahores

Mutual exclusion with sempahores

2

5

6 7 8

9

10

11

12

13

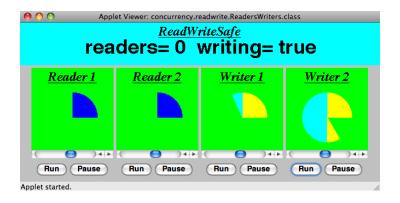

14

15

16 17

```
class MutexLoop implements Runnable {
    Semaphore mutex;
    MutexLoop (Semaphore sema) {mutex=sema;}
    public void run() {
      try {
        while(true) {
           while (! ThreadPanel. rotate());
            // get mutual exclusion
            mutex.down();
            while(ThreadPanel.rotate()); //critical section
            //release mutual exclusion
            mutex.up();
      } catch(InterruptedException e){}
```

Readers and writers problem (again...)

A shared database is accessed by two kinds of processes. Readers execute transactions that examine the database while Writers both examine and update the database. A Writer must have exclusive access to the database; any number of Readers may concurrently access it.

Interface R/W

```
interface ReadWrite {
   public void acquireRead() throws InterruptedException;
   public void releaseRead();
   public void acquireWrite() throws InterruptedException;
   public void releaseWrite();
}
```

2

4 5 6

7 8 9

10 11

12

13

14

15

16

17 18

```
class Reader implements Runnable {
   ReadWrite monitor ;
  Reader(ReadWrite monitor) {
     monitor = monitor;
    public void run() {
      trv {
        while(true) {
            while (! ThreadPanel . rotate ());
            // begin critical section
            monitor .acquireRead();
            while (ThreadPanel.rotate());
            monitor . releaseRead();
      } catch (InterruptedException e){}
```

Writer client code

7 8 9

10 11

12

13

14

15

16

17 18

```
class Writer implements Runnable {
   ReadWrite monitor ;
  Writer(ReadWrite monitor) {
    monitor = monitor;
    public void run() {
      trv {
        while(true) {
            while (! ThreadPanel . rotate ());
            // begin critical section
            monitor .acquireWrite();
            while (ThreadPanel.rotate());
            monitor . releaseWrite();
      } catch (InterruptedException e){}
```

R/W monitor (regulate readers)

2

3

4 5 6

7

8

13

14 15 16

17 18

```
class ReadWriteSafe implements ReadWrite {
  private int readers =0;
 private boolean writing = false;
  public synchronized void acquireRead()
             throws InterruptedException {
   while (writing) wait();
   ++readers:
  public synchronized void releaseRead() {
  — readers:
   if (readers==0) notifyAll();
  public synchronized void acquireWrite() {...}
  public synchronized void releaseWrite() {...}
```

6 7 8

9

10

11

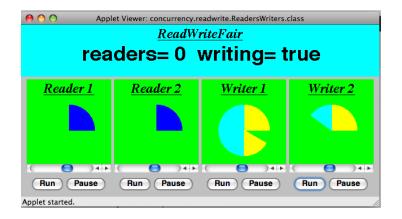

12

13 14 15

16

17

```
class ReadWriteSafe implements ReadWrite {
 private int readers = 0;
 private boolean writing = false;
 public synchronized void acquireRead() {...}
 public synchronized void releaseRead() {...}
 public synchronized void acquireWrite()
              throws Interrupted Exception {
   while (readers >0 || writing) wait();
   writing = true;
 public synchronized void releaseWrite() {
    writing = false;
   notifyAll();
```

"Fairness": regulating readers

```
class ReadWriteFair implements ReadWrite {
2
3
        private int readers = 0:
4
        private boolean writing = false;
5
        private int waiting W = 0; // no of waiting Writers.
6
        private boolean readersturn = false;
7
8
        synchronized public void acquireRead()
9
        throws Interrupted Exception {
10
            while (writing || (waiting W > 0 &&!readersturn)) wait();
11
12
            ++readers:
13
14
        synchronized public void releaseRead() {
15
            - - readers;
16
            readersturn=false;
17
            if(readers==0) notifyAll();
18
19
20
        synchronized public void acquireWrite() {...}
21
        synchronized public void releaseWrite() {...}
22
23
```

"Fairness": regulating writers

```
class ReadWriteFair implements ReadWrite {
2
3
        private int readers = 0:
4
        private boolean writing = false;
5
        private int waiting W = 0; // no of waiting Writers.
6
        private boolean readersturn = false;
7
8
        synchronized public void acquireRead() {...}
9
        synchronized public void releaseRead() {...}
10
11
12
        synchronized public void acquireWrite()
        throws Interrupted Exception {
13
14
            ++waitingW;
            while (readers >0 || writing) wait();
15
            ---waitingW; writing = true;
16
17
18
        synchronized public void releaseWrite() {
19
            writing = false; readersturn=true;
20
            notifyAll();
21
22
23
```

Readers and Writers problem

DEMO

Java concurrency

- there's (much) more to it than what we discussed (synchronization, monitors) (see java.util.concurrency)
- Java's memory model: since Java 1: loooong, hot debate
- connections to
 - GUI-programming (swing/awt/events) and to
 - RMI etc.
- major clean-up/repair since Java 5
- better "thread management"
- Lock class (allowing new Lock() and non block-structured locking)
- one simplification here: Java has a (complex!) weak memory model (out-of-order execution, compiler optimization)
- not discussed here volatile

General advice

shared, mutable state is more than a bit tricky, a watch out!

- work thread-local if possible
- make variables immutable if possible
- keep things local: encapsulate state
- learn from tried-and-tested concurrent design patterns

golden rule

never, ever allow (real, unprotected) races

- unfortunately: no silver bullet
- for instance: "synchronize everything as much as possible": not just inefficient, but mostly nonsense
- \Rightarrow concurrent programmig remains a bit of an art

and pointer aliasing and a weak memory model makes it worse.

Message passing and channels

INF4140 - Models of concurrency Message passing and channels

Høsten 2014

17. Oct. 2014

Outline

Course overview:

- Part I: concurrent programming; programming with shared variables
- Part II: "distributed" programming

Outline: asynchronous and synchronous message passing

- Concurrent vs. distributed programming³⁷
- Asynchronous message passing: channels, messages, primitives
- Example: filters and sorting networks
- From monitors to client–server applications
- Comparison of message passing and monitors
- About synchronous message passing

³⁷The dividing line is not absolute. One can make perfectly good use of channels and message passing also in a non-distributed setting.

Shared memory vs. distributed memory

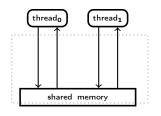

more traditional system architectures have one shared memory:

- many processors access the same physical memory
- example: fileserver with many processors on one motherboard

Distributed memory architectures:

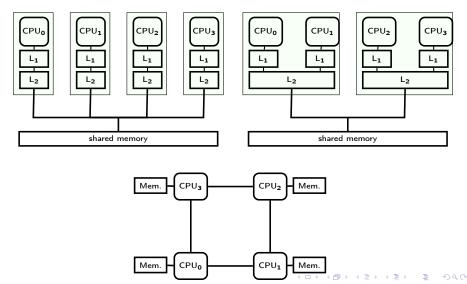

- Processor has private memory and communicates over a "network" (inter-connect)
- Examples:
 - Multicomputer: asynchronous multi-processor with distributed memory (typically contained inside one case)
 - Workstation clusters: PC's in a local network
 - Grid system: machines on the Internet, resource sharing
 - cloud computing: cloud storage service
 - NUMA-architectures
 - cluster computing . . .

Shared memory concurrency in the real world

- the memory architecture does not reflect reality
- out-of-order executions:
 - modern systems: complex memory hierarchies, caches, buffers. . .
 - compiler optimizations,

SMP, multi-core architecture, and NUMA

Concurrent vs. distributed programming

Concurrent programming:

- Processors share one memory
- Processors communicate via reading and writing of shared variables

Distributed programming:

- Memory is distributed
 - ⇒ processes cannot share variables (directly)
- Processes communicate by sending and receiving messages via shared channels
 - or (in future lectures): communication via RPC and rendezvous

Asynchronous message passing: channel abstraction

Channel: abstraction, e.g., of a physical communication network³⁸

- One—way from sender(s) to receiver(s)
- unbounded FIFO (queue) of waiting messages
- preserves message order
- atomic access
- error–free
- typed

Variants: errors possible, untyped, ...

Asynchronous message passing: primitives

Channel declaration

chan
$$c(type_1id_1, ..., type_nid_n);$$

Messages: *n*-tuples of values of the respective types communication primitives:

- send c(expr₁,..., expr_n);
 Non-blocking, i.e. asynchronous
- receive $c(\text{var}_1, \dots, \text{var}_n)$; Blocking: receiver waits until message is sent on the channel
- empty (c);True if channel is empty

$$\begin{array}{c|c} \hline & P1 & \xrightarrow{\text{send}} & \xrightarrow{\text{c}} & \xrightarrow{\text{receive}} & \hline & P2 & \\ \hline \end{array}$$

Example: message passing

```
(x,y) = 
A \longrightarrow \frac{\text{foo}}{} \qquad \text{receive} \qquad B
```

```
chan foo(int);

process A {
    send foo(1);
    send foo(2);
}

chan foo(int);

process B {
    receive foo(x);
    receive foo(y);
}
```

Example: message passing

```
(x,y) = (1,2)
A \longrightarrow \frac{\text{foo}}{\longrightarrow} \text{receive} B
```

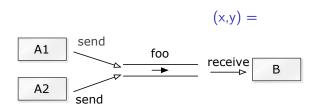

```
chan foo(int);

process A {
    send foo(1);
    send foo(2);
}

chan foo(int);

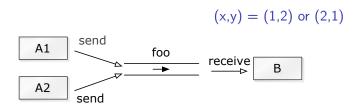

process B {
    receive foo(x);
    receive foo(y);
}
```

Example: shared channel

```
process A1 {
    send foo(1);
    }
    process A2 {
        send foo(2);
        11
    }
    process B {
```

Example: shared channel

```
process A1 {
    send foo(1);
    }
    | process A2 {
        send foo(2);
        11
        | receive foo(x);
        receive foo(y);
        |
        | receive foo(y);
        |
        | receive foo(y);
        |
        | process B {
```

Asynchronous message passing and semaphores

Comparison with general semaphores:

```
egin{array}{lll} {\it channel} & \simeq & {\it semaphore} \ {\it send} & \simeq & {\it V} \ {\it receive} & \simeq & {\it P} \ \end{array}
```

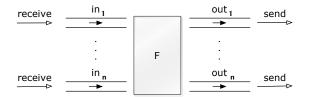

Number of messages in queue = value of semaphore

(Ignores content of messages)

Filters: one-way interaction

Filter **F**

- = process which:
 - receives messages on input channels,
 - sends messages on output channels, and
 - output is a function of the input (and the initial state).

- A filter is specified as a predicate.
- Some computations can naturally be seen as a composition of filters.
- cf. stream processing/programming (feedback loops) and

Example: A single filter process

Problem: Sort a list of *n* numbers into ascending order.

process **Sort** with input channels **input** and output channel **output**.

Define:

n : number of values sent to **output**.

sent[i]: i'th value sent to **output**.

Sort predicate

```
\forall i : 1 \leq i < n. \ (sent[i] \leq sent[i+1])
```

∧ values sent to output are a permutation of values from input.

Filter for merging of streams

Problem: Merge two sorted input streams into one sorted stream.

Process Merge with input channels in₁ and in₂ and output channel out:

Special value **EOS** marks the end of a stream.

Define:

n : number of values sent to **out**.

sent[i] : i'th value sent to out.

The following shall hold when **Merge** *terminates*:

```
in_1 and in_2 are empty \land sent[n+1] = EOS
```

 $\land \quad \forall i : 1 \leq i < n(sent[i] \leq sent[i+1])$

∧ values sent to **out** are a permutation of values from in₁ and in₂

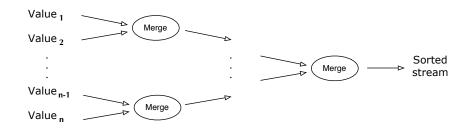

Example: Merge process

```
chan in1(int), in2(int), out(int);
2
3
   process Merge {
      int v1, v2;
4
      receive in1(v1);
                                      # read the first two
5
      receive in2(v2);
                                      # input values
6
7
8
      while (v1 \neq EOS and v2 \neq EOS) {
        if (v1 < v2)
9
10
         \{  send out(v1); receive in1(v1); \}
        else
                                     \# (v1 > v2)
11
12
          { send out(v2); receive in2(v2); }
13
14
                                     # consume the rest
15
                                     # of the non-empty input channel
16
      while (v2 \neq EOS)
17
        \{ send out(v2); receive in2(v2); \}
18
      while (v1 \neq EOS)
19
        { send out(v1); receive in1(v1); }
20
      send out(EOS); # add special value to out
21
22
```

Sorting network

We now build a network that sorts *n* numbers.

We use a collection of Merge processes with tables of shared input and output channels.

(Assume: number of input values n is a power of 2)

Client-server applications using messages

Server: process, repeatedly handling requests from client processes.

Goal: Programming client and server systems with asynchronous message passing.

```
      1 | chan request(int clientID , ...), reply[n](...);

      3 | client nr. i
      server int id; # client id.

      5 | client nr. i
      while(true) { # server loop receive request(id, vars);

      9 | : receive reply[i](vars); ← send reply[id](results);
      : send reply[id](results);
```

Monitor implemented using message passing

Classical monitor:

- controlled access to shared resource
- Permanent variables (monitor variables): safeguard the resource state
- access to a resource via *procedures*
- procedures: executed under mutual exclusion
- condition variables for synchronization

also implementable by server process + message passing Called "active monitor" in the book: active process (loop), instead of passive procedures.³⁹

³⁹In practice: server may spawn local threads, one per request. E > 4 E > 5000 (2000)

Allocator for multiple—unit resources

Multiple-unit resource: a resource consisting of multiple units

Examples: memory blocks, file blocks.

Users (clients) need resources, use them, and return them to the allocator ("free" the resources).

- here simplification: users get and free *one* resource at a time.
- two versions:
 - 1. monitor
 - 2. server and client processes, message passing

Allocator as monitor

Uses "passing the condition" pattern \Rightarrow simplifies later translation to a server process

Unallocated (free) units are represented as a set, type set, with operations insert and remove.

Recap: "semaphore monitor" with "passing the condition"

```
monitor Semaphore fifo \{ \# monitor invariant : s \ge 0 \}
                         # value of the semaphore
      int s := 0:
2
                            # wait condition
      cond pos;
3
4
      procedure Psem() {
5
        if (s=0)
6
            wait (pos);
7
8
        else
9
            s := s - 1
10
11
12
      procedure Vsem() {
13
14
           empty(pos)
             s := s + 1
15
        else
16
             signal(pos);
17
18
19
```

(Fig. 5.3 in Andrews [Andrews, 2000])

Allocator as a monitor

```
monitor Resource Allocator {
     int avail := MAXUNITS;
2
      set units := ... # initial values;
3
     cond free; # signalled when process wants a unit
5
      procedure acquire(int &id) { # var.parameter
6
        if (avail = 0)
7
          wait (free);
8
        else
9
10
          avail := avail -1:
        remove(units, id);
11
12
13
14
      procedure release(int id) {
        insert(units, id);
15
        if (empty(free))
16
          avail := avail + 1:
17
        else
18
          signal(free);
                                    # passing the condition
19
20
21
```

- 1. interface and "data structure"
- 2. control structure: nested if-statement (2 levels):
- 3. synchronization, scheduling, and mutex

- 1. interface and "data structure"
 - 1.1 allocator with two types of operations: get unit, free unit
 - 1.2 1 request channel⁴⁰ \Rightarrow must be *encoded* in the arguments to a request.
- 2. control structure: nested if-statement (2 levels):
- 3. synchronization, scheduling, and mutex

- 1. interface and "data structure"
 - 1.1 allocator with two types of operations: get unit, free unit
 - 1.2 1 request channel⁴⁰ \Rightarrow must be *encoded* in the arguments to a request.
- 2. control structure: nested if-statement (2 levels):
 - 2.1 first checks type operation,
 - 2.2 proceeds correspondingly to monitor-if.
- 3. synchronization, scheduling, and mutex

- 1. interface and "data structure"
 - 1.1 allocator with two types of operations: get unit, free unit
 - 1.2 1 request channel⁴⁰ \Rightarrow must be *encoded* in the arguments to a request.
- 2. control structure: nested if-statement (2 levels):
 - 2.1 first checks type operation,
 - 2.2 proceeds correspondingly to monitor-if.
- 3. synchronization, scheduling, and mutex
 - 3.1 cannot wait (wait(free)) when no unit is free.
 - 3.2 must save the request and return to it later ⇒ queue of pending requests (queue; insert, remove).
 - 3.3 request: "synchronous/blocking" call \Rightarrow "ack"-message back
 - 3.4 no internal parallelism \Rightarrow mutex

⁴⁰Alternatives exist

Channel declarations:

```
type op_kind = enum(ACQUIRE, RELEASE);
chan request(int clientID, op_kind kind, int unitID);
chan reply[n](int unitID);
```

Allocator: client processes

```
process Client[i = 0 to n-1] {
   int unitID;
   send request(i, ACQUIRE, 0)  # make request
   receive reply[i](unitID);  # works as 'if synchronous''
   ...  # use resource unitID
   send request(i, RELEASE, unitID); # free resource
   ...
}
```

(Fig. 7.7(b) in Andrews)

Allocator: server process

```
process Resource Allocator {
     int avail := MAXUNITS;
2
     set units := ...
                                # initial value
3
                                 # initially empty
     queue pending;
     int clientID, unitID; op kind kind; ...
5
     while (true) {
6
7
       receive request(clientID, kind, unitID);
       if (kind = ACQUIRE) {
8
         if (avail = 0) # save request
9
            insert(pending, clientID);
10
         else { # perform request now
11
              avail:= avail -1;
12
              remove(units, unitID);
13
14
             send reply[clientID](unitID);
15
16
                                  # kind = RELEASE
       else {
17
         if empty(pending) { # return units
18
            avail := avail+1; insert(units, unitID);
19
         } else {
                                  # allocates to waiting client
20
              remove(pending, clientID);
21
             send reply[clientID](unitID);
22
                                  # Fig. 7.7 in Andrews (rewritten)
23
```

Allocator as a monitor

```
monitor Resource Allocator {
     int avail := MAXUNITS;
2
      set units := ... # initial values;
3
     cond free; # signalled when process wants a unit
5
      procedure acquire(int &id) { # var.parameter
6
        if (avail = 0)
7
          wait (free);
8
        else
9
10
          avail := avail -1:
        remove(units, id);
11
12
13
14
      procedure release(int id) {
        insert(units, id);
15
        if (empty(free))
16
          avail := avail + 1:
17
        else
18
          signal(free);
                                    # passing the condition
19
20
21
```

Duality: monitors, message passing

monitor-based programs	message-based programs
monitor variables	local server variables
process-IDs	request channel, operation types
procedure call	send request(), receive reply[i]()
go into a monitor	receive request()
procedure return	send reply[i]()
wait statement	save pending requests in a queue
signal statement	<pre>get and process pending request (reply)</pre>
procedure body	branches in if statement wrt. op. type

Synchronous message passing

Primitives:

New primitive for sending:
 synch send c(expr₁,..., expr_n);

Blocking send:

- sender waits until message is received by channel,
- i.e. sender and receiver "synchronize" sending and receiving of message
- Otherwise: like asynchronous message passing: receive c(var₁,...,var_n); empty(c);

Synchronous message passing: discussion

Advantages:

- Gives maximum size of channel.
 Sender synchronises with receiver
 - ⇒ receiver has at most 1 pending message per channel per sender
 - \Rightarrow sender has at most 1 unsent message

Disadvantages:

- reduced parallellism: when 2 processes communicate, 1 is always blocked.
- higher risk of deadlock.

Example: blocking with synchronous message passing

```
chan values(int);
2
3
    process Producer {
      int data[n];
      for [i = 0 \text{ to } n-1] {
5
         ... # computation ...;
6
        synch send values(data[i]);
7
8
9
    process Consumer {
10
      int results[n];
11
      for [i = 0 \text{ to } n-1] {
12
        receive values(results[i]);
13
         ... # computation ...;
14
15
```

Example: blocking with synchronous message passing

```
chan values(int);
2
3
    process Producer {
      int data[n];
      for [i = 0 \text{ to } n-1] {
5
         ... # computation ...;
6
        synch send values(data[i]);
7
8
9
    process Consumer {
10
      int results[n];
11
      for [i = 0 \text{ to } n-1] {
12
        receive values(results[i]);
13
         ... # computation ...;
14
15
```

Assume both producer and consumer vary in time complexity.

Communication using synch_send/receive will block.

With asynchronous message passing, the waiting is reduced.

Example:

```
chan in1(int), in2(int);
2
    process P1 {
      int v1 = 1, v2;
4
      synch send in2(v1);
5
6
7
8
9
      receive in1(v2);
    process P2 {
10
      int v1, v2 = 2;
      synch send in1(v2);
11
      receive in2(v1);
12
13
```

Example: deadlock using synchronous message passing

```
chan in1(int), in2(int);
2
   process P1 {
      int v1 = 1, v2;
      synch send in2(v1);
      receive in1(v2);
6
7
8
9
   process P2 {
      int v1, v2 = 2;
10
      synch send in1(v2);
11
      receive in2(v1);
12
13
```

P1 and P2 block on synch send – deadlock.
One process must be modified to do receive first

⇒ asymmetric solution.

Example: deadlock using synchronous message passing

```
chan in1(int), in2(int);
2
   process P1 {
      int v1 = 1, v2;
      synch send in2(v1);
      receive in1(v2);
6
7
8
   process P2 {
      int v1, v2 = 2;
10
      synch send in1(v2);
11
      receive in2(v1);
12
13
```

P1 and P2 block on synch send – deadlock.
One process must be modified to do receive first
⇒ asymmetric solution.

With asynchronous message passing (send) all goes well.

INF4140 - Models of concurrency RPC and Rendezvous

INF4140

24 Oct. 2014

RPC and Rendezvous

Outline

- More on asynchronous message passing
 - interacting processes with different patterns of communication
 - summary
- remote procedure calls
 - · concept, syntax, and meaning
 - examples: time server, merge filters, exchanging values
- Rendez-vous
 - concept, syntax, and meaning
 - examples: buffer, time server, exchanging values
- combinations of RPC, rendezvous and message passing
 - Examples: bounded buffer, readers/writers

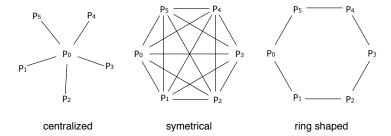

Interacting peers (processes): exchanging values example

Look at processes as peers.

Example: Exchanging values

- Consider n processes $P[0], \ldots, P[n-1], n > 1$
- every process has a number, stored in local variable v
- Goal: all processes knows the largest and smallest number.
- simplistic problem, but "characteristic" of distributed computation and information distribution

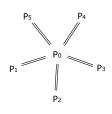

Different communication patters

Centralized solution

Process P[0] is the coordinator process:

- P[0] does the calculation
- The other processes sends their values to P[0] and waits for a reply.

Number of messages:⁴¹ (number of send:)
$$P[0]: \quad n-1$$

$$P[1], \ldots, P[n-1]: \quad (n-1)$$

$$Total: \quad (n-1) + (n-1) = 2(n-1) \text{ messages}$$
repeated "computation"

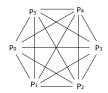

Number of channels: n

 $^{^{41}}$ For now in the pics: 1 line = 1 message (not 1 channel), but the notation in the pics is not 100% consistent.

Centralized solution: code

```
chan values(int),
        results [1..n-1](int smallest, int largest);
2
3
   process P[0] { # coordinator process
4
     int v := \ldots;
5
     int new, smallest := v, largest := v; # initialization
6
     # get values and store the largest and smallest
7
8
     for [i = 1 \text{ to } n-1] {
       receive values(new);
9
       10
       if (new > largest) largest := new;
11
12
     # send results
13
14
     for [i = 1 \text{ to } n-1]
       send results[i](smallest, largest);
15
16
   process P[i = 1 \text{ to } n-1] {
17
     int v := ...;
18
     int smallest, largest;
19
20
     send values(v);
21
     receive results[i](smallest, largest);}
22
   # Fig. 7.11 in Andrews (corrected a bug)
23
```

Symmetric solution

"Single-programme, multiple data (SPMD)"-solution:

Each process executes the same code and shares the results with all other processes.

Number of messages:

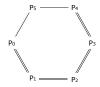

n processes sending n-1 messages each, Total: n(n-1) messages.

Number of (bi-directional) channels: n(n-1)

Symmetric solution: code

```
chan values[n](int);
2
3
    process P[i = 0 \text{ to } n-1] {
      int v := \dots;
      int new, smallest := v, largest := v;
5
6
7
      # send v to all n-1 other processes
8
      for [j = 0 \text{ to } n-1 \text{ st } j \neq i]
        send values[i](v);
9
10
      # get n-1 values
11
12
      # and store the smallest and largest.
      for [j = 1 \text{ to } n-1] { # j not used in the loop
13
        receive values[i](new);
14
        if (new < smallest) smallest := new;
15
        if (new > largest) largest := new;
16
17
     # Fig. 7.12 from Andrews
18
```

Ring solution

Almost symmetrical, except P[0], P[n-2] and P[n-1].

Each process executes the same code and sends the results to the *next* process (if necessary).

Number of messages:

P[0]: 2
P[1], ..., P[
$$n-3$$
]: $(n-3) \times 2$
P[$n-2$]: 1
P[$n-1$]: 1
 $2+2(n-3)+1+1=2(n-1)$ messages sent.

Number of channels: n.

Ring solution: code (1)

```
chan values[n](int smallest, int largest);
2
3
   process P[0] { # starts the exchange
     int v := \dots;
     int smallest := v, largest := v;
5
     # send v to the next process, P[1]
6
     send values[1](smallest, largest);
     # get the global smallest and largest from P[n-1]
     # and send them to P[1]
     receive values[0](smallest, largest);
10
     send values[1](smallest, largest);
11
12
```

Ring solution: code (2)

```
process P[i = 1 \text{ to } n-1] {
2
     int v := ...:
     int smallest , largest;
3
     # get smallest and largest so far,
           and update them by comparing them to v
5
      receive values[i](smallest, largest)
6
7
      if (v < smallest) smallest := v;</pre>
8
      if (v > largest) largest := v;
     # forward the result, and wait for the global result
9
     send values [(i+1) mod n](smallest, largest);
10
      if (i < n-1)
11
        receive values[i](smallest, largest);
12
     # forward the global result, but not from P[n-1] to P[0]
13
     if (i < n-2)
14
        send values[i+1](smallest, largest);
15
    # Fig. 7.13 from Andrews (modified)
16
```

Message passing: Summary

Message passing: well suited to programming filters and interacting peers (where processes communicates one way by one or more channels).

May be used for client/server applications, but:

- Each client must have its own reply channel
- In general: two way communication needs two channels
- ⇒ many channels

RPC and rendezvous are better suited for client/server applications.

Remote Procedure Call: main idea

```
CALLER
called
at computer A at computer B
```

RPC (cont.)

RPC: combines elements from monitors and message passing

- As ordinary procedure call, but caller and callee may be on different machines.⁴²
- Caller: blocked until called procedure is done, as with monitor calls and synchronous message passing.
- Asynchronous programming: not supported directly
- A new process handles each call.
- Potentially two way communication: caller sends arguments and receives return values.

RPC: module, procedure, process

Module: new program component – contains both

procedures and processes.

```
module M
headers of exported operations;

body
variable declarations;
initialization code;
procedures for exported operations;
local procedures and processes;
end M
```

Modules may be executed on different machines

M has: procedures and processes

- may share variables
- execute concurrently ⇒ must be synchronized to achieve mutex
- May only communicate with processes in M' by procedures exported by M'

RPC: operations

```
Declaration of operation O:
            op O(formal parameters.) [returns result];
Implementation of operation O:
     proc O(formal identifiers.) [ returns result identifier]{
       declaration of local variables:
       statements
Call of operation O in module M:<sup>43</sup>
                        call M.O(arguments)
Processes: as before.
```

⁴³Cf. static/class methods

Synchronization in modules

- RPC: primarily a communication mechanism
- within the module: in principle allowed:
 - more than one process
 - shared data
- ⇒ need for synchronization
 - two approaches
 - 1. "implicit":
 - as in monitors: mutex built-in
 - additionally condition variables (or semaphores)
 - 2. "explicit":44
 - user-programmed mutex and synchronization (like semaphorse, local monitors etc)

⁴⁴assumed in the following

Example: Time server (RPC)

- module providing timing services to processes in other modules.
- interface: two visible operations:
 - get_time() returns int returns time of day
 - delay(int interval) let the caller sleep a given number of time units
- multiple clients: may call get_time and delay at the same time
- ⇒ Need to protect the variables.
 - internal process that gets interrupts from machine clock and updates tod

Time server code (rpc)

end TimeServer

21

```
module TimeServer
     op get time() returns int;
     op delay(int interval);
3
   body
     int tod := 0; # time of day
5
6
     sem m := 1; # for mutex
     sem d[n] := ([n] \ 0); \# for delayed processes
7
8
     queue of (int waketime, int process id) napQ;
     ## when m = 1, tod < waketime for delayed processes
9
     proc get time() returns time { time := tod; }
10
11
     proc delay(int interval) {
12
            \# assume unique myid and i [0,n-1]
       P(m);
13
       int waketime := tod + interval:
14
         insert (waketime, myid) at appropriate place in napQ;
15
      V(m);
16
       P(d[myid]); # Wait to be awoken
17
18
     process Clock ...
19
```

マロティ団ティミティミト ヨーの

Time server code: clock process

Rendezvous

RPC:

- offers inter-module communication
- synchronization (often): must be programmed explicitly

Rendezvous:

- Known from the language Ada (US DoD)
- Combines communication and synchronization between processes
- No new process created for each call
- instead: perform 'rendezvous' with existing process
- Operations are executed one at the time

synch_send and receive may be considered as primitive rendezvous. cf. also join-synchronization

Rendezvous: main idea

```
CALLER
caller
at computer A at computer B
```

Rendezvous: module declaration

3

6 7

8

9

10 11

12 13

14

15

16

```
module M
  op O_1(types);
  op O_n(types);
body
  process P<sub>1</sub> {
     variable declarations;
     while (true)
                                                      # standard pattern
       in O_1 (formals) and B_1 \rightarrow S_1;
          O_n (formals) and B_n \rightarrow S_n;
       пi
  ... other processes
end M
```

Calls and input statements

Call:

```
1 call O_i (expr<sub>1</sub>,..., expr<sub>m</sub>);
```

Input statement, multiple guarded expressions:

```
in O_1(v_1, \dots v_{m_1}) and B_1 \rightarrow S_1;

\vdots
O_n(v_1, \dots v_{m_n}) and B_n \rightarrow S_n;

ni
```

The guard consists of:

- \bullet and B_i synchronization expression (optional)
- S_i statements (one or more)

The variables v_1, \ldots, v_{m_i} may be referred by B_i and S_i may read/write to them.⁴⁵

⁴⁵once again: no side-effects in B!!!

Semantics of input statement

Consider the following:

```
 \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \end{bmatrix} \begin{bmatrix} \text{in } \dots \\ O_i(v_i, \dots, v_{m_i}) \text{ and } B_i \longrightarrow S_i; \\ \dots \\ \text{ni} \end{bmatrix}
```

The guard *succeeds* when O_i is called and B_i is true (or omitted).

Execution of the in statement:

- Delays until a guard succeeds
- If more than one guard succeed, the oldest call is served 46
- Values are returned to the caller
- The the call- and in-statements terminates

⁴⁶this may be changed using additional syntax (by), see [Andrews, 2000].

Different variants

- different versions of rendezvous, depending on the language
- origin: ADA (accept-statement) (see [Andrews, 2000, Section 8.6])
- design variation points
 - synchronization expressions or not?
 - scheduling expressions or not?
 - can the guard inspect the values for input variables or not?
 - non-determinism
 - checking for absence of messages? priority
 - checking in more than one operation?

Bounded buffer with rendezvous

3

5 6

7

8

9

10

11

12

13

14 15

16

```
module BoundedBuffer
  op deposit(TypeT), fetch(result TypeT);
body
  process Buffer {
    elem buf[n];
    int front := 0, rear := 0, count := 0;
    while (true)
      in deposit(item) and count < n ->
            buf[rear] := item; count++;
                  rear := (rear + 1) \mod n;
      [] fetch (item) and count > 0 ->
                 item := buf[front]; count--;
                 front := (front+1) \mod n;
      пi
end BoundedBuffer # Fig. 8.5 of Andrews
```

Example: time server (rendezvous)

3

6

7

8

9

10

11

12 13 14

15

```
module TimeServer
  op get time() returns int;
  op delay(int); # absolute waketime as argument
  op tick(); # called by the clock interrupt handler
body
  process Timer {
    int tod := 0;
    start timer:
    while (true)
      in get time() returns time -> time := tod;
      [] delay(waketime) and waketime <= tod -> skip;
      [] tick() \rightarrow \{ tod++; restart timer; \}
end TimeServer # Fig. 8.7 of Andrews
```

RPC, rendezvous and message passing

We do now have several combinations:

invocation	service	effect
call	proc	procedure call (RPC)
call	in	rendezvous
send	proc	dynamic process creation
send	in	asynchronous message passing

RPC, rendezvous and message passing

We do now have several combinations:

invocation	service	effect
call	proc	procedure call (RPC)
call	in	rendezvous
send	proc	dynamic process creation
send	in	asynchronous message passing

in addition (not in Andrews)

• asynchronous procedure call, wait-by-necessity, futures

Rendezvous, message passing and semaphores

Comparing input statements and receive:

in
$$O(a_1, \ldots, a_n)$$
 -> v_1 = a_1, \ldots, v_n = a_n ni \iff receive $O(v_1, \ldots, v_n)$

Comparing message passing and semaphores:

send O() and receive O()
$$\iff$$
 V(O) and P(O)

Bounded buffer: procedures and "semaphores (simulated by channels)"

```
module BoundedBuffer
     op deposit(typeT), fetch(result typeT);
   body
3
     elem buf[n];
4
     int front = 0, rear = 0;
5
     # local operation to simulate semaphores
6
     op empty(), full(), mutexD(), mutexF();
7
                                                      // operations
     send mutexD(); send mutexF(); # init. "semaphores" to 1
8
     for [i = 1 to n] # init. empty-"semaphore" to n
9
       send empty();
10
11
     proc deposit(item) {
12
       receive empty(); receive mutexD();
13
       buf[rear] = item; rear = (rear+1) mod n;
14
       send mutexD(); send full();
15
16
     proc fetch(item) {
17
       receive full(); receive mutexF();
18
       item = buf[front]; front = (front+1) mod n;
19
       send mutexF(); send empty();
20
21
   end BoundedBuffer # Fig. 8.12 of Andrews
22
```

The primitive ? O in rendezvous

New primitive on operations, similar to empty(...) for condition variables and channels.

?O means number of pending invocations of operation O.

Useful in the input statement to give priority:

Here O_1 has a higher priority than O_2 .

Readers and writers

```
module ReadersWriters
     op read(result types); # uses RPC
2
                       # uses rendezvous
     op write(types);
3
   body
     op startread(), endread(); # local ops.
5
      ... database (DB)...;
6
7
8
     proc read(vars) {
        call startread(); # get read access
9
        ... read vars from DB ...;
10
       send endread(); # free DB
11
12
      process Writer {
13
14
        int nr := 0:
       while (true)
15
          in startread() -> nr++;
16
          [] endread() \rightarrow nr--;
17
          [] write(vars) and nr = 0 \rightarrow
18
               ... write vars to DB ... :
19
          ni
20
21
   end ReadersWriters
22
```

Readers and writers: prioritize writers

```
module ReadersWriters
     op read(result typeT); # uses RPC
2
                       # uses rendezvous
     op write(typeT);
3
   body
     op startread(), endread(); # local ops.
5
      ... database (DB)...;
6
7
8
     proc read(vars) {
        call startread(); # get read access
9
        ... read vars from DB ...;
10
        send endread(); # free DB
11
12
      process Writer {
13
14
        int nr := 0:
        while (true)
15
        in startread() and ?write = 0 \rightarrow nr++;
16
          [] endread() \rightarrow nr--;
17
          [] write(vars) and nr = 0 \rightarrow
18
                ... write vars to DB ... ;
19
          пi
20
21
   end ReadersWriters
22
```

Asynchronous Communication I

INF4140 - Models of concurrency Asynchronous Communication, lecture 10

INF4140

7.11.2014

Asynchronous Communication: Semantics, specification and reasoning

Where are we?

- part one: shared variable systems
 - programming
 - synchronization
 - reasoning by invariants and Hoare logic
- part two: communicating systems
 - message passing
 - channels
 - rendezvous

What is the connection?

- What is the semantic understanding of message passing?
- How can we understand concurrency?
- How to understand a system by looking at each component?
- How to specify and reason about asynchronous systems?

Overview

Clarifying the semantic questions above, by means of histories:

- describing interaction
- capturing interleaving semantics for concurrent systems
- Focus: asynchronous communication systems without channels

Plan today

- histories from the outside view of components
 - describing overall understanding of a (sub)system
- Histories from the inside view of a component
 - describing local understanding of a single process
- The connection between the inside and outside view
 - the composition rule

What kind of system? Agent network systems

Two kinds of settings for concurrent systems, based on the notion of:

- processes without self identity, but with named channels.
 Channels often FIFO.
- object (agent) with self identity, but without channels, sending messages to named objects through a network. In general, a network gives no FIFO guarantee, nor guarantee of successful transmission.

We use the latter here, since it is a very general setting. The process/channel setting may be obtained by representing each combination of object and message kind as a channel.

in the following we consider agent/network systems!

Programming asynchronous agent systems

New syntax statements for sending and receiving:

- send statement: send B: m(e)
 means that the current agent sends message m to agent B
 where e is an (optional) list of actual parameters.
- fixed receive statement: await B: m(w) wait for a message m from a specific agent B, and receive parameters in the variable list w. We say that the message is then consumed.
- open receive statement: await X? m(w)
 wait for a message m from any agent X and receive
 parameters in w (consuming the message).
 The variable X will be set to the agent that sent the message.
- choice operator [] to select between alternative statement lists, starting with receive statements.

Here m is a message name, B the name of an agent, e expressions, X and w variables.

Example: Coin machine

Consider an agent *C* which changes "5 krone" coins and "1 krone" coins into "10 krone" coins. It receives *five* and *one* messages and sends out *ten* messages as soon as possible, in the sense that the number of messages sent out should equal the total amount of kroner received divided by 10.

We imagine here a fixed user agent U, both producing the *five* and *one* messages and consuming the *ten* messages. The code of the agent C is given below, using b (balance) as a local variable initialized to 0.

Example: Coin machine (Cont)

2

3

4 5

6

7

8

10

```
loop
  while b < 10
  ob
    (await U: five; b:=b+5)
    (await U: one; b:=b+1)
  od:
  send U:ten;
  b := b - 10
end
```

- choice operator []⁴⁷
 - selects 1 enabled branch
 - non-deterministic choice if both branches are enabled

⁴⁷In the literature, also + as notation can often be found \bigcirc + + \bigcirc \longrightarrow + \bigcirc \longrightarrow + \bigcirc \longrightarrow + \bigcirc \bigcirc \longrightarrow + \bigcirc \longrightarrow + \bigcirc \bigcirc \longrightarrow \longrightarrow \longrightarrow \longrightarrow \longrightarrow \longrightarrow \longrightarrow \longrightarrow \bigcirc

Interleaving semantics of concurrent systems

- behavior of a concurrent system: may be described as set of executions,
- 1 execution: sequence of atomic interaction events,
- other names for it: trace, history, execution, (interaction) sequence ... 48

Interleaving semantics

Concurrency is expressed by the set of all possible interleavings.

- remember also: "sequential consistency" from the WMM part.
- note: for each interaction sequence, all interactions are ordered sequentially, and their "visible" concurrency

⁴⁸message sequence (charts) in UML etc.

Regular expressions

 very well known and widely used "format" to descibe "languages" (= sets finite "words" over given a given "alphabet")

A way to describe (sets of) traces

Example (Reg-Expr)

- a, b: atomic interactions.
- Assume them to "run" concurrently
- \Rightarrow two possible interleavings, described by

$$[[a.b] + [b.a]] \tag{3}$$

Parallel composition of a^* and b^* :

$$(a+b)^* (4)$$

Remark: notation for reg-expr's

Different notations exist. E.g.: some write a|b for the alternative/non-deterministic choice between a and b. We use + instead

- to avoid confusion with parallel composition
- be consistent with common use of regexp. for describing concurrent behavior

Safety and liveness & traces

We may let each interaction sequence reflect all interactions in an execution, called the trace, and the set of all possible traces is then called the trace set.

- terminating system: finite traces⁴⁹
- non-terminating systems: infinite traces
- trace set semantics in the general case: both finite and infinite traces
- 2 conceptually important classes of properties⁵⁰
 - safety ("nothing wrong will happen")
 - liveness ("something good will happen")

⁴⁹Be aware: typically an *infinite* set of finite traces.

⁵⁰Safety etc. it's not a property, it's a "property/class of properties" \geq >

Safety and liveness & histories

- often: concentrate on finite traces
- reasons
 - conceptually/theoretically simpler
 - connection to monitoring
 - connection to checking (violations of) safety prop's
- our terminology: history = trace up to a given execution point (thus finite)
- note: In contrast to the book, histories are here finite initial parts of a trace (prefixes)
- sets of histories are

prefix closed

if a history h is in the set, then every prefix (initial part) of h is also in the set.

• sets of histories: can be used capture safety, but not liveness

Consider a system of two agents, A and B, where agent A says "hi-B" repeatedly until B replies "hi-A".

	traces	histories
a "sloppy" B may or may not	$hi_B^{\infty} + hi_B^+ hi_A$	$hi_B^* + hi_B^+ hi_A$
give a reply, in which case		
there will be an infinite trace		
with only "hi-B"		
a "lazy" B will reply even-		
tually, but there is no limit		
on how long A may need to		
wait. Thus, each trace will		
end with "hia" after finitely		
many " <i>hi_B</i> "'s.		
an "eager" B will reply within		'
a fixed number of "hi _B "'s, for		
instance before A says "hi _B "		
three times.		

• a "sloppy" B may or may not give a reply, in which case there will be an infinite trace with only "hi-B" (here comma denotes union).

Consider a system of two agents, A and B, where agent A says "hi-B" repeatedly until B replies "hi-A".

	traces	histories

give a reply, in which case		
there will be an infinite trace		
with only "hi-B"		
a "lazy" <i>B</i> will reply even-		
tually, but there is no limit		
on how long A may need to		
wait. Thus, each trace will		
end with " hi_A " after finitely		
many " <i>hi_B</i> "'s.		
an "eager" B will reply within		'
a fixed number of "hi _B "'s, for		
instance before A says "hi _B "		

• a "sloppy" B may or may not give a reply, in which case there will be an infinite trace with only "hi-B" (here comma denotes union).

Trace set: $\{[hi_B]^{\infty}\}, \{[hi_B]^+ [hi_A]\}$ Histories: $\{[hi_B]^*\}, \{[hi_B]^+ [hi_A]\}$

Histories

Let use the following conventions

- events x : Event is an event,
- set of events: A: 2^{Event}
- history *h* : *Hist*

A set of events is assumed to be fixed.

Definition (Histories)

Histories (over the given set of events) is given inductively over the constructors ϵ (empty history) and _; _ (appending of an event to the right of the history)

Functions over histories

```
function
            type
                                          the empty history (constructor)

ightarrow Hist
   ; : Hist * Event \rightarrow Hist append right (constructor)
   # : Hist

ightarrow Nat length
  \_/\_ : Hist * Set \rightarrow Hist projection by set of events
 \_ \le \_ : \textit{Hist} * \textit{Hist} \rightarrow \textit{Bool} prefix relation
  <: Hist * Hist \rightarrow Bool strict prefix relation
Inductive definitions (inductive wrt. \varepsilon and ; ):
             = 0
        \#\epsilon
        \#(h; x) = \#h + 1
       \epsilon/A
             =\epsilon
       (h;x)/s =if x \in A then (h/s); x else (h/s) fi
 h \le h' = (h = h') \lor h < h'
        h < \varepsilon = false
        h < (h'; x) = h < h'
```

Invariants and Prefix Closed Trace Sets

May use invariants to define trace sets:

A (history) invariant *I* is a predicate over a histories, supposed to hold at all times:

"At any point in an execution h the property I(h) is satisfied"

It defines the following set:

$$\{h \mid I(h)\}\tag{5}$$

- mostly interested in prefix-closed invariants!
- a history invariant is historically monotonic:

$$h \le h' \Rightarrow (I(h') \Rightarrow I(h))$$
 (6)

• I history-monotonic ⇒ set from equation (5) prefix closed

Remark:

A non-monotonic predicate I may be transformed to a monotonic one I':

Semantics: Outside view: global histories over events

Consider asynchronous communication by messages from one agent to another: Since message passing may take some time, the sending and receiving of a message m are semantically seen as two distinct atomic interaction events of type Event:

- $A \uparrow B$: m denotes that A sends message m to B
- $A \downarrow B$: m denotes that B receives (consumes) message m from A

A global history, H, is a finite sequence of such events, requiring that it is legal, i.e. each reception is preceded by a corresponding send-event.

For instance, the history

```
[(A \uparrow B : hi), (A \uparrow B : hi), (A \downarrow B : hi), (A \uparrow B : hi), (B \uparrow A : hi)]
```

is legal and expresses that A has sent "hi" three times and that B has received one of these and has replied "hi".

Note: a concrete message may also have parameters, say messagename(parameterlist)

Coin Machine Example: Events

```
U \uparrow C: five —— U sends the message "five" to C U \downarrow C: five —— C consumes the message "five" U \uparrow C: one —— C sends the message "one to C U \downarrow C: one —— C consumes the message "one" C \uparrow U: ten —— C sends the message "ten" C \downarrow U: ten —— C consumes the message "ten"
```

Legal histories

- note all global sequences/histories "make sense"
- depens on the programming language/communciation model
- sometimes called well-definedness, well-formedness or similar
- $legal : Hist \rightarrow Bool$

Definition (Legal history)

```
legal(\epsilon) = true legal(h; (A \uparrow B : m)) = legal(h) legal(h; (A \downarrow B : m)) = legal(h) \land \#(h/\{A \downarrow B : m\}) < \#(h/\{A \uparrow B : m\})
```

where m is message and h a history.

• should *m* include parameters, legality ensures that the values received are the same as those sent.

Example (coin machine C user U):

$$[(U \uparrow C : five), (U \uparrow C : five), (U \downarrow C : five), (U \downarrow C : five), (C \uparrow U : ten)]$$
⁵⁷⁸

Outside view: logging the global history

How to "calculate" the global history at run-time:

- introduce a global variable H,
- initialize: to empty sequence
- for each execution of a send statement in A, update H by

$$H := H; (A \uparrow B : m)$$

where B is the destination and m is the I message

• for each execution of a receive statement in B, update H by

$$H := H; (A \downarrow B : m)$$

where m is the message and A the sender. The message must be of the kind requested by B.

Outside View: Global Properties

Global invariant: By a predicate *I* on the global history, we may specify desired system behavior:

"at any point in an execution H the property I(H) is satisfied"

- By logging the history at run-time, as above, we may monitor an executing system. When I(H) is violated we may
 - report it
 - stop the system, or
 - interact with the system (for inst. through fault handling)
- How to prove such properties by analysing the program?
- How can we monitor, or prove correctness properties, component-wise?

Semantics: Inside view: Local histories

Definition (Local events)

The events visible to an agent A, denoted α_A , are the events local to A, i.e.:

- $A \uparrow B$: m: any send-events from A. (output by A)
- $B \downarrow A$: m: any reception by A. (input by A)

Definition (Local history)

Given a global history: The local history of A, written h_A , is the subsequence of all events visible to A

• Conjecture: Correspondence between global and local view:

$$h_{\Delta} = H/\alpha_{\Delta}$$

- i.e. at any point in an execution the history observed locally in $\cal A$ is the projection to $\cal A$ -events of the history observed globally.
- Each event is visible to one, and only one, agent!

Coin Machine Example: Local Events

The events visible to C are:

```
U\downarrow C: five U\downarrow C: one U\downarrow C: consumes the message "one" U\downarrow C: consumes the message "ten"
```

The events visible to U are:

```
U \uparrow C: five U sends the message "five" to C U \uparrow C: one U sends the message "one to C C \downarrow U: ten U consumes the message "ten"
```

How to relate local and global views

From global specification to implementation:

First, set up the goal of a system: by one or more global histories. Then implement it. For each component: use the global histories to obtain a local specification, guiding the implementation work. "construction from specifications"

From implementation to global specification:

First, make or reuse components.

Use the local knowledge for the desired components to obtain global knowledge.

Working with invariants:

The specifications may be given as invariants over the history.

- Global invariant: in terms of all events in the system
- Local invariant (for each agent): in terms of events visible to the agent

Need composition rules connecting local and global invariants.

Example revisited: Sloppy coin machine

9

10

```
loop
  while b < 10
  do
    (await U: five; b:=b+5)
    (await U:one; b:=b+1)
  od:
  send U:ten;
  b := b - 10
end
```

interactions visible to ${\it C}$ (i.e. those that may show up in the local history):

```
U\downarrow C: five —— C consumes the message "five" U\downarrow C: one —— C consumes the message "one" C\uparrow U: ten —— C sends the message "ten"
```

Coin machine example: Loop invariants

Loop invariant for the outer loop:

$$sum(h/\downarrow) = sum(h/\uparrow) + b \land 0 \le b < 5 \tag{7}$$

where *sum* (the sum of values in the messages) is defined as follows:

$$sum(\varepsilon) = 0$$

$$sum(h; (...: five)) = sum(h) + 5$$

$$sum(h; (...: one)) = sum(h) + 1$$

$$sum(h; (...: ten)) = sum(h) + 10$$

Loop invariant for the inner loop:

$$sum(h/\downarrow) = sum(h/\uparrow) + b \land 0 \le b < 15$$
 (8)

Histories: from inside to outside view

From local histories to global history: if we know all the local histories h_{Ai} in a system (i = 1...n), we have

$$legal(H) \wedge_i h_{A_i} = H/\alpha_{A_i}$$

i.e. the global history H must be legal and correspond to all the local histories. This may be used to reason about the global history. **Local invariant:** a local specification of A_i is given by a predicate on the local history $I_{A_i}(h_{A_i})$ describing a property which holds before all local interaction points.

I may have the form of an implication, expressing the output events from A_i depends on a condition on its input events.

From local invariants to a global invariant:

if each agent satisfies $I_{A_i}(h_{A_i})$, the total system will satisfy:

$$legal(H) \wedge_i I_{A_i}(H/\alpha_{A_i})$$

Coin machine example: from local to global invariant

before each send/receive: (see eq. (8))

$$sum(h/\downarrow) = sum(h/\uparrow) + b \land 0 \le b < 15$$

Local Invariant of C in terms of h alone:

$$I_C(h) = \exists b. \ (sum(h/\downarrow) = sum(h/\uparrow) + b \ \land \ 0 \le b < 15)$$
 (9)

$$I_C(h) = 0 \le sum(h/\downarrow) - sum(h/\uparrow) < 15$$
 (10)

For a global history H ($h = H/\alpha_C$):

$$I_C(H/\alpha_C) = 0 \le sum(H/\alpha_C/\downarrow) - sum(H/\alpha_C/\uparrow) < 15$$
 (11)

Shorthand notation:

$$I_C(H/\alpha_C) = 0 \le sum(H/\downarrow C) - sum(H/C\uparrow) < 15$$

Coin machine example: from local to global invariant

ullet Local Invariant of a careful user U (with exact change):

$$\begin{split} I_U(h) &= 0 \leq sum(h/\uparrow) - sum(h/\downarrow) \leq 10 \\ I_U(H/\alpha_U) &= 0 \leq sum(H/U\uparrow) - sum(H/\downarrow U) \leq 10 \end{split}$$

• Global Invariant of the system *U* and *C*:

$$I(H) = legal(H) \wedge I_C(H/\alpha_C) \wedge I_U(H/\alpha_U)$$
 (12)

implying:

Overall

$$0 \le sum(H/U \downarrow C) - sum(H/C \uparrow U) \le sum(H/U \uparrow C) - sum(H/C \downarrow U) \le 10$$

```
since legal(H) gives:

sum(H/U\downarrow C) \leq sum(H/U\uparrow C) and

sum(H/C\downarrow U) \leq sum(H/C\uparrow U).
```

So, globally, this system will have balance ≤ 10 .

Coin machine example: Loop invariants (Alternative)

Loop invariant for the outer loop:

$$rec(h) = sent(h) + b \land 0 \le b < 5$$

where *rec* (the total amount received) and *sent* (the total amount sent) are defined as follows:

```
rec(\varepsilon) = 0
rec(h; (U \downarrow C : five)) = rec(h) + 5
rec(h; (U \downarrow C : one)) = rec(h) + 1
rec(h; (C \uparrow U : ten)) = rec(h)
sent(\varepsilon) = 0
sent(h; (U \downarrow C : five)) = sent(h)
sent(h; (U \downarrow C : one)) = sent(h)
sent(h; (C \uparrow U : ten)) = sent(h) + 10
```

Loop invariant for the inner loop:

$$rec(h) = sent(h) + b \land 0 \le b < 15$$

Legality

The above definition of legality reflects networks where you may not assume that messages sent will be delivered, and where the order of messages sent need not be the same as the order received. Perfect networks may be reflected by a stronger concept of legality (see next slide).

Remark: In "black-box" specifications, we consider observable events only, abstracting away from internal events. Then, legality of sending may be strengthened:

$$legal(h; (A \uparrow B : m)) = legal(h) \land A \neq B$$

Using Legality to Model Network Properties

If the network delivers messages in a FIFO fashion, one could capture this by strengthening the legality-concept suitably, requiring

$$sendevents(h/\downarrow) \leq h/\uparrow$$

where the projections h/\uparrow and h/\downarrow denote the subsequence of messages sent and received, respectively, and *sendevents* converts receive events to the corresponding send events.

```
sendevents(\varepsilon) = \varepsilon
sendevents(h; (A \uparrow B : m)) = sendevents(h)
sendevents(h; (A \downarrow B : m)) = sendevents(h); (A \uparrow B : m)
```

Channel-oriented systems can be mimicked by requiring FIFO ordering of communication for each pair of agents:

$$sendevents(h/A \downarrow B) \leq h/A \uparrow B$$

where $A \downarrow B$ denotes the set of receive-events with A as source and B as destination, and similarly for $A \uparrow B$.

Asynchronous Communication II

INF4140 - Models of concurrency Asynchronous Communication, lecture 11

INF4140

14.11.2014

Overview: Last time

- semantics: histories and trace sets
- specification: invariants over histories
 - global invariants
 - local invariants
 - the connection between local and global histories
- example: Coin machine
 - the main program
 - formulating local invariants

Overview: Today

- Analysis of send/await statements
- Verifying local history invariants
- example: Coin Machine
 - proving loop invariants
 - the local invariant and a global invariant
- example: Mini bank

Agent/network systems (Repetition)

We consider general agent/network systems:

- Concurrent agents:
 - with self identity
 - no variables shared between agents
 - communication by message passing
- Network:
 - no channels
 - no FIFO guarantee
 - no guarantee of successful transmission

Programming asynchronous agent systems

New syntax statements for sending and receiving:

- send statement: send B: m(e)
 means that the current agent sends message m to agent B
 where e is an (optional) list of actual parameters.
- fixed receive statement: await B: m(w) wait for a message m from a specific agent B, and receive parameters in the variable list w. We say that the message is then consumed.
- open receive statement: await X? m(w)
 wait for a message m from any agent X and receive
 parameters in w (consuming the message).
 The variable X will be set to the agent that sent the message.
- choice operator [] to select between alternative statement lists, starting with receive statements.

Here m is a message name, B the name of an agent, e expressions, X and w variables.

Local reasoning by Hoare logic (a.k.a program logic)

We adapt Hoare logic to reason about local histories in an agent A:

- Introducing a local (logical) variable h, initialized to empty ε
 - h represents the local history of A
- For **send/await**-statement: define the effect on *h*.
 - extending the h with the corresponding event
- Local reasoning: we do not know the global invariant
 - For await: unknown parameter values
 - For open receive: unknown sender
- ⇒ use non-deterministic assignment

$$x := some$$
 (13)

where variable x may be given any (type correct) value

Local invariant reasoning by Hoare Logic

each send statement send B: m in A is treated as:

$$h := (h; A \uparrow B : m) \tag{14}$$

• each fixed receive statement await $B: m(\vec{x})$ in A^{51} is treated as

$$w := some ; h := (h; B \downarrow A : m(\vec{x}))$$
 (15)

the usage of $\vec{x} :=$ **some** expresses that A may receive any values for the receive parameters

• each open receive statement await $X ? m(\vec{x})$ in A is treated as

$$X :=$$
some ; await $X : m(\vec{x})$ (16)

where the usage of X :=some expresses that A may receive the message from any agent

⁵¹where \vec{x} is a sequence of variables

Rule for non-deterministic assignments

Non-det assignment

```
\frac{}{\{ \ \forall x \ . \ Q \ \} \ x := \mathbf{some} \ \{ \ Q \ \}}  ND-Assign
```

- as said: await/send have been expressed by manipulating h, using non-det assignments
- ⇒ rules for await/send statements

Derived Hoare rules for send and receive

```
\frac{1}{\{\ Q_{h\leftarrow h;A\upharpoonright B:m}\ \} \ \text{send} \ B: m\ \{\ Q\ \}} \ \text{Send}} \frac{1}{\{\ \forall \vec{x}\ .\ Q_{h\leftarrow h;B\downharpoonright A:m(\vec{x})}\ \} \ \text{await} \ B: m(\vec{x})\ \{\ Q\ \}} \ \text{Receive}_{1}} \frac{1}{\{\ \forall \vec{x}, X\ .\ Q_{h\leftarrow h;X\downharpoonright A:m(\vec{x})}\ \} \ \text{await} \ X?\ m(\vec{x})\ \{\ Q\ \}} \ \text{Receive}_{2}}
```

- As before: A is current agent/object, h the local history
- We assume that neither B nor X occur in \vec{x} , and that \vec{x} is a list of distinct variables.
- No shared variables. ⇒ no interference, and Hoare reasoning can be done as usual in the sequential setting!
- Simplified version, if no parameters in await:

Hoare rules for local reasoning

The Hoare rule for non-deterministic choice ([]) is

Rule for []

$$\frac{ \{ P_1 \} S_1 \{ Q \} \qquad \{ P_2 \} S_2 \{ Q \} }{ \{ P_1 \land P_2 \} (S_1[\]S_2) \{ Q \} } \text{ Nondet}$$

Remark: We may reason similarly backwards over conditionals:⁵²

$$\frac{\{\ P_1\ \}\ S_1\ \{\ Q\ \} \qquad \{\ P_2\ \}\ S_2\ \{\ Q\ \}}{\{\ (b\Rightarrow P_1)\land (\neg b\Rightarrow P_2)\ \}\ \text{if}\quad b\ \ \text{then}\quad S_1\ \ \text{else}\quad S_2\ \ \text{fi}\ \ \{\ Q\ \}}}\ \text{If'}$$

⁵²We used actually a different formulation for the rule for conditionals. Both formulations are equivalent in the sense that (together with the other rules, in particular Consequence, one can prove the same properties.

Example: Coin machine

Consider an agent *C* which changes "5 krone" coins and "1 krone" coins into "10 krone" coins. It receives *five* and *one* messages and sends out *ten* messages as soon as possible, in the sense that the number of messages sent out should equal the total amount of kroner received divided by 10.

We imagine here a fixed user agent U, both producing the *five* and *one* messages and consuming the *ten* messages. The code of the agent C is given below, using b (balance) as a local variable initialized to 0.

Example: Coin machine (Cont)

2

3

4 5

6

7

8

10

```
loop
  while b < 10
  ob
    (await U: five; b:=b+5)
    (await U: one; b:=b+1)
  od:
  send U:ten;
  b := b - 10
end
```

- choice operator []⁴⁷
 - selects 1 enabled branch
 - non-deterministic choice if both branches are enabled

⁴⁷In the literature, also + as notation can often be found \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc

Coin Machine Example: Events

```
U \uparrow C: five — U sends the message "five" to C U \downarrow C: five — C consumes the message "five"

U \uparrow C: one — U sends the message "one to C U \downarrow C: one — C consumes the message "one"

C \uparrow U: ten — C sends the message "ten"

C \downarrow U: ten — U consumes the message "ten"
```

Coin machine: local events

Invariants may refer to the local history h, which is the sequence of events visible to C that have occurred so far. The events visible to C are:

```
U \downarrow C: five -- C consumes the message "five" U \downarrow C: one -- C consumes the message "one" C \uparrow U: ten -- C sends the message "ten"
```

Coin machine example: Loop invariants

Loop invariant for the outer loop:

$$sum(h/\downarrow) = sum(h/\uparrow) + b \land 0 \le b < 5 \tag{7}$$

where *sum* (the sum of values in the messages) is defined as follows:

$$sum(\varepsilon) = 0$$

$$sum(h; (...: five)) = sum(h) + 5$$

$$sum(h; (...: one)) = sum(h) + 1$$

$$sum(h; (...: ten)) = sum(h) + 10$$

Loop invariant for the inner loop:

$$sum(h/\downarrow) = sum(h/\uparrow) + b \land 0 \le b < 15$$
 (8)

let I_i ("inner invariant") abbreviate equation (8)

```
while b < 10 { b \le 10 \land I_i }
            \{(I_{i b \leftarrow (b+5)})_{h \leftarrow h: U \mid C: five} \land (I_{i b \leftarrow (b+1)})_{h \leftarrow h: U \mid C: one}\}
             do
 4
5
                   ( await U: five; { I_{i5\leftarrow b+1} }
 6
                    b := b + 5
 8
               (await U: one; b:=b+1)
              \{I_i\}
           od:
10
           \{ I_i \land b \ge 10 \}
11
           \{(I_{ob\leftarrow b-10})_{h\leftarrow h:C\cap U:ten}\}
12
           send U:ten:
13
```

Must prove the implication:

$$b < 10 \land I_i \Rightarrow \left(I_{i \ b \leftarrow (b+5)}\right)_{h \leftarrow h; U \mid C: five} \land \left(I_{i \ b \leftarrow (b+1)}\right)_{h \leftarrow h; U \mid C: one}$$

note: From precondition I_i for the loop, we have $I_i \wedge b \geq 10$ as the postcondition to the inner loop.

Outer loop

```
{ l<sub>o</sub> }
       loop
 3
              \{I_o\}
              while b < 10 { b \le 10 \land I_i }
 5
              \{(I_{i b \leftarrow (b+5)})_{b \leftarrow b \cdot U \mid C \cdot five} \land (I_{i b \leftarrow (b+1)})_{b \leftarrow b \cdot U \mid C \cdot one}\}
              do
 8
                     ( await U: five; \{I_{i5\leftarrow b+1}\}
                       b := b + 5
 9
10
                (await U: one; b:=b+1)
11
12
13
            od:
            \{ I_i \land b > 10 \}
14
            \{(l_{ob\leftarrow b-10})_{h\leftarrow h;C\uparrow U:ten}\}
15
            send U:ten;
16
17
            { l<sub>ob←b-10</sub> }
            b := b - 10
18
19
            { I<sub>o</sub> }
20
       end
```

Verification conditions (as usual):

```
• I_o \Rightarrow I_i, and
• I_i \land b \ge 10 \Rightarrow (I_o \underset{b \leftarrow (b-10)}{b \leftarrow b \cdot CM \cdot ten})
```

Local history invariant

For each agent (A):

- Predicate $I_A(h)$ over the local communication history (h)
- Describes interactions between A and the surrounding agents
- Must be maintained by all history extensions in A
- Last week: Local history invariants for the different agents may be composed, giving a global invariant

```
Verification idea: "induction":
```

Init: Ensure that $I_A(h)$ holds initially (i.e., with $h = \varepsilon$)

Preservation: Ensure that $I_A(h)$ holds after each

send/await-statement, assuming that $I_A(h)$ holds

before each such statement

Local history invariant reasoning

- to prove properties of the code in agent A
- for instance: loop invariants etc
- the conditions may refer to the local state \vec{x} (a list of variables) and the local history h, e.g., $Q(\vec{x}, h)$.

The local history invariant $I_A(h)$:

- must hold immediately *after* each send/receive
- \Rightarrow if reasoning gives the condition Q(v, h) immediately after a send or receive statement, we basically need to ensure:

$$Q(\vec{x},h) \Rightarrow I_A(h) \tag{17}$$

- we may assume that the invariant is satisfied immediately before each send/receive point.
- we may also assume that the last event of h is the send/receive event.

Proving the local history invariant

- I_A(_): local history invariant of A
- first conjunct h = ...: specifies last communication step
- I_A(h'): assumption that invariant holds before the comm.-statement
- 3 communication/sync. statements: send B: m(e), await $B m(\vec{x})$, and await $X? m(\vec{x}) \Rightarrow$

3 kinds of verification conditions

$$(h = (h'; A \uparrow B : m(e)) \land I_A(h') \land Q(\vec{x}, h)) \Rightarrow I_A(h)$$
 (18)

$$(h = (h'; B \downarrow A : m(\vec{y})) \land I_A(h') \land Q(\vec{x}, h)) \Rightarrow I_A(h)$$
 (19)

$$(h = (h'; X \downarrow A : m(\vec{y})) \land I_A(h') \land Q(\vec{x}, h)) \Rightarrow I_A(h)$$
 (20)

in all three cases: Q is the condition right after the send-, resp. the await-statement

Coin machine example: local history invariant

For the coin machine C, consider the local history invariant $I_C(h)$ from last week (see equation (10)):

$$I_C(h) = 0 \le sum(h/\downarrow) - sum(h/\uparrow) < 15$$

Consider the statement send *U*: ten in *C*

- Hoare analysis of the outer loop gave the condition $l_{o\ b\leftarrow(b-10)}$ immediately after the statement
- history ends with the event C↑U: ten
- \Rightarrow Verification condition, corresponding to equation (18):

$$h = h'; (C \uparrow U : ten) \land I_C(h') \land I_o \bowtie_{b \leftarrow (b-10)} \Rightarrow I_C(h)$$
 (21)

Coin machine example: local history invariant

Expanding I_c and I_o in the VC from equation (21), and using definition of sum and using $(sum(h'/\downarrow) - sum(h'/\uparrow) = b$ in the last step

$$\begin{array}{l} h = h'; (C \uparrow U : ten) \land \\ I_{C}(h') \land \\ I_{o \ b \leftarrow (b-10)} \\ \Rightarrow I_{C}(h) \\ \hline h = h'; (C \uparrow U : ten) \land \\ (0 \leq sum(h'/\downarrow) - sum(h'/\uparrow) < 15) \land \\ (sum(h/\downarrow) = sum(h/\uparrow) + b - 10 \land 0 \leq b - 10 < 5) \\ \Rightarrow 0 \leq sum(h/\downarrow) - sum(h/\uparrow) < 15 \\ \hline h = h'; (C \uparrow U : ten) \land \\ (0 \leq sum(h'/\downarrow) - sum(h'/\uparrow) < 15) \land \\ (sum(h'/\downarrow) = sum(h'/\uparrow) + 10 + b - 10 \land 0 \leq b - 10 < 5) \\ \Rightarrow 0 \leq sum(h'/\downarrow) - sum(h'/\uparrow) - 10 < 15 \\ \hline (0 \leq b < 15) \land 0 \leq b - 10 < 5) \\ \Rightarrow 0 \leq b = 10 < 15 \\ \hline \end{array}$$

Coin Machine Example: Summary

Correctness proofs (bottom-up):

- code
- loop invariants (Hoare analysis)
- local history invariant
- verification of local history invariant based on the Hoare analysis

Note: The []-construct was useful (basically necessary) for programming service-oriented systems, and had a simple proof rule.

Example: "Mini bank" (ATM): Informal specification

Client cycle: The client *C* is making these messages

 put in card, give pin, give amount to withdraw, take cash, take card

Mini Bank cycle: The mini bank M is making these messages to client: ask for pin, ask for withdrawal, give cash, return card

to central bank: request of withdrawal

Central Bank cycle: The central bank B is making these messages to mini bank: grant a request for payment, or deny it

There may be many mini banks talking to the same central bank, and there may be many clients using each mini bank (but the mini bank must handle one client at a time).

Mini bank example: Global histories

```
Consider a client C, mini bank M and central bank B:

Example of successful cycle:

[ C \updownarrow M : card \_in(n), M \updownarrow C : pin, C \updownarrow M : pin(x), M \updownarrow C : amount, C \updownarrow M : amount(y), M \updownarrow B : request(n, x, y), B \updownarrow M : grant, M \updownarrow C : cash(y), M \updownarrow C : card \_out]

where n is name, x pin code, and y cash amount, provided by clients.

Example of unsuccessful cycle:

[ C \updownarrow M : card \_in(n), M \updownarrow C : pin, C \updownarrow M : pin(x), M \updownarrow C : amount, C \updownarrow M : amount(y), M \updownarrow B : request(n, x, y), B \updownarrow M : deny, M \updownarrow C : card \_out]

Notation: A \updownarrow B : m denotes the sequence A \uparrow B : m, A \downarrow B : m
```

Mini bank example: Local histories (1)

From the global histories above, we may extract the corresponding local histories:

The successful cycle:

```
• Client: [C \uparrow M : card\_in(n), M \downarrow C : pin, C \uparrow M : pin(x), M \downarrow C : amount, C \uparrow M : amount(y), M \downarrow C : cash(y), M \downarrow C : card\_out]
```

- Mini Bank: $[C \downarrow M : card_in(n), M \uparrow C : pin, C \downarrow M : pin(x), M \uparrow C : amount, C \downarrow M : amount(y), M \uparrow B : request(n, x, y), B \downarrow M : grant, M \uparrow C : cash(y), M \uparrow C : card_out]$
- Central Bank: $[M \downarrow B : request(n, x, y), B \uparrow M : grant]$

The local histories may be used as guidelines when implementing the different agents.

Mini bank example: Local histories (2)

The unsuccessful cycle:

- Client: $[C \uparrow M : card_in(n), M \downarrow C : pin, C \uparrow M : pin(x), M \downarrow C : amount, C \uparrow M : amount(y), M \downarrow C : card_out]$
- Mini Bank: $[C \downarrow M : card_in(n), M \uparrow C : pin, C \downarrow M : pin(x), M \uparrow C : amount, C \downarrow M : amount(y), M \uparrow B : request(n, x, y), B \downarrow M : deny, M \uparrow C : card_out]$
- Central Bank: $[M \downarrow B : request(n, x, y), B \uparrow M : deny]$

Note: many other executions possible, say when clients behaves differently, difficult to describe all at a global level (remember the formula of week 1).

Mini bank example: implementation of Central Bank

Sketch of simple central bank.

Program variables:

```
pin -- array of pin codes, indexed by client names
bal -- array of account balances, indexed by client names
```

```
X : Agent, n: Client_Name, x: Pin_Code, y: Natural
```

```
Loop
    await X?request(n,x,y);
    if pin[n]=x and bal[n]>y
    then bal[n]:=bal[n]-y;
        send X:grant;
else send X:deny
fi
end
```

Note: the mini bank X may vary with each iteration.

Mini bank example: Central Bank (B)

Consider the (extended) regular expression *CycleB* defined by:

$$[X \downarrow B : request(n, x, y), [B \uparrow X : grant + B \uparrow X : deny]$$
some $X, n, x, y]^*$

- with + for choice, [...]* for repetition
- Defines cycles: request answered with either grant or deny
- notation [regExp some X, n, x, y]* means that the values of X, n, x, and y are fixed in each cycle, but may vary from cycle to cycle.

Notation: Given an extended regular expression R.

Let h is R denote that h matches the structure described by R.

Example (for events a, b, and c):

- we have (a; b; a; b) is $[a, b]^*$
- we have (a; c; a; b) is $[a, [b|c]]^*$
- we do not have (a; b; a) is $[a, b]^*$

```
Loop invariant of Central Bank (B):
Let Cycle<sub>B</sub> denote the regular expression:
[X \downarrow B : request(n, x, y), [B \uparrow X : grant + B \uparrow X : deny] some X, n, x, y *
Loop invariant: h is Cycle<sub>B</sub>
Proof of loop invariant (entry condition): Must prove that it is
satisfied initially: \varepsilon is Cycle<sub>B</sub>, which is trivial.
Proof of loop invariant (invariance):
 loop {his Cycle<sub>R</sub>}
     await X?request(n,x,y);
     if pin[n]=x and bal[n]>y
          then bal[n]:=bal[n]-y; send X:grant;
          else send X:deny
      fi
 {his Cycle<sub>R</sub>}
 end
```

Loop invariant of the central bank (B):

2

5

6 7 8

9

10

11 12

13

14

15 16

```
loop
   { h is Cycle<sub>B</sub> }
   \{ \forall X, n, x, y \text{ if } pin[n] = x \land bal[n] > y \text{ then } h_1'' \text{ is } Cycle_B \text{ else } h_2'' \text{ is } Cycle_B \}
   await X?request(n,x,y);
      { if pin[n] = x \land bal[n] > y then h'_1 is Cycle_B else h'_2 is Cycle_B }
           pin[n]=x and bal[n]>y
     then bal[n] := bal[n] - y;
              { (h; B \uparrow X : grant) is Cycle_B }
              send X: grant;
              { (h; B \uparrow X : grant) is Cycle_B }
     else
        { (h; B \uparrow X : deny) is Cycle_B }
   fi
   { h is Cycle<sub>B</sub> }
end
```

```
h_1'' = h; X \downarrow B : request(n, x, y); B \uparrow X : grant

h_1' = h; B \uparrow X : grant
```

Analogously (with deny) for h'_2 and h''_2

Hoare analysis of central bank loop (cont.)

Verification condition:

```
h is Cycle_B \Rightarrow \forall X, n, x, y if pin[n] = x \land bal[n] > y
                     then (h; X \downarrow B : request(n, x, y); B \uparrow X : grant) is Cycle_B
                     else (h; X \downarrow B : request(n, x, y); B \uparrow X : deny) is Cycle_B
where Cycle<sub>B</sub> is
```

$$[X \downarrow B : request(n, x, y), [B \uparrow X : grant + B \uparrow X : deny]$$
some $X, n, x, y]^*$

The condition follows by the general rule (regExp R and events a and b):

$$h$$
 is $R^* \wedge (a; b)$ is $R \Rightarrow (h; a; b)$ is R^*

 $(X \downarrow B : request(n, x, y); B \uparrow X : grant)$ is $Cycle_B$ $(X \downarrow B : request(n, x, y); B \uparrow X : deny)$ is $Cycle_B$

Local history invariant for the central bank (B)

Cycle_B is

$$[X \downarrow B : request(n, x, y), [B \uparrow X : grant + B \uparrow X : deny]$$
some $X, n, x, y]^*$

Define the history invariant for B by:

$$h \leq Cycle_B$$

Let $h \leq R$ denote that h is a prefix of the structure described by R.

- intuition: if $h \le R$ we may find some extension h' such that (h; h') is R
- h is $R \Rightarrow h \leq R$ (but not vice versa)
- (h; a) is $R \Rightarrow h \leq R$
- Example: $(a; b; a) \leq [a, b]^*$

Central Bank: Verification of the local history invariant

$h \leq Cycle_B$

- As before, we need to ensure that the history invariant is implied after each send/receive statement.
- Here it is enough to assume the conditions after each send/receive statement in the verification of the loop invariant

This gives 2 proof conditions:

- 1. after send grant/deny (i.e. after fi) h is $Cycle_B \Rightarrow h \leq Cycle_B$ which is trivial.
- 2. after await request
- if ... then $(h; B \uparrow X : grant)$ is $Cycle_B$ else $(h; B \uparrow X : deny)$ is $Cycle_B$ $\Rightarrow h \leq Cycle_B$ which follows from (h; a) is $R \Rightarrow h \leq R$.
- **Note:** We have now proved that the implementation of B satisfies the local history invariant, $h \leq Cycle_B$.

Mini bank example: Local invariant of Client (C)

```
Cycle_C: \\ [ C^{\uparrow}X : card\_in(n) \\ + X \downarrow C : pin, C^{\uparrow}X : pin(x) \\ + X \downarrow C : amount, C^{\uparrow}X : amount(y') \\ + X \downarrow C : cash(y) \\ + X \downarrow C : card\_out \quad \textbf{some} \quad X, y, y' ]^* \\ \text{History invariant:} \\ h_C \leq Cycle_C
```

Note: The values of C, n and x are fixed from cycle to cycle. **Note:** The client is willing to receive cash and cards, and give card, at any time, and will respond to pin, and amount messages from a mini bank X in a sensible way, without knowing the protocol of the particular mini bank. This is captured by + for different choices.

Mini bank example: Local invariant for Mini bank (M)

```
Cycle<sub>M</sub>:

[ C \downarrow M : card\_in(n), M \uparrow C : pin, C \downarrow M : pin(x),

M \uparrow C : amount, C \downarrow M : amount(y),

if y \leq 0 then \varepsilon else

M \uparrow B : request(n, x, y), [B \downarrow M : deny + B \downarrow M : grant, M \uparrow C : cash(y) ] fi ,

M \uparrow C : card\_out some C, n, x, y ]*

History invariant:

h_M \leq Cycle_M
```

Note: communication with a fixed central bank. The client may vary with each cycle.

Mini bank example: obtaining a global invariant

```
Consider the parallel composition of C, B, M. Global invariant: legal(H) \land H/\alpha_C \le Cycle_C \land H/\alpha_M \le Cycle_M \land H/\alpha_B \le Cycle_B
```

Assuming no other agents, this invariant may almost be formulated by: $H \le [C \updownarrow M : card \quad in(n), M \updownarrow C : pin, C \updownarrow M : pin(x),$

```
M \updownarrow C: amount, C \updownarrow M: amount(y),

if y \leq 0 then M \updownarrow C: card_out

else M \updownarrow B: request(n, x, y), [B \updownarrow M: deny, M \updownarrow C: card_out

+ B \updownarrow M: grant, M \uparrow C: cash(y), [M \downarrow C: cash(y) ||| M \updownarrow C: card_out|| fi
```

some n, x, y]* where ||| gives all possible interleavings. However, we have no guarantee

that the cash and the card events are received by C before another cycle starts. Any next client may actually take the cash of C.

For proper clients it works OK, but improper clients may cause the Mini Bank to misbehave. Need to incorporate assumptions on the clients, or make an improved mini bank.

Improved mini bank based on a discussion of the global invariant

The analysis so far has discovered some weaknesses:

- The mini bank does not know when the client has taken his cash, and it may even start a new cycle with another client before the cash of the previous cycle is removed. This may be undesired, and we may introduce a new event, say cash_taken from C to M, representing the removal of cash by the client. (This will enable the mini bank to decide to take the cash back within a given amount of time.)
- A similar discussion applies to the removal of the card, and one may introduce a new event, say card_taken from C to M, so that the mini bank knows when a card has been removed. (This will enable the mini bank to decide to take the card back within a given amount of time.)
- A client may send improper or unexpected events. These may be lying in the network unless the mini bank receives them, and say, ignores them.
 For instance an old misplaced amount message may be received in (and interfere with) a later cycle. An improved mini bank could react to such message by terminating the cycle, and in between cycles it could ignore all messages (except card in).

Summary

Concurrent agent systems, without network restrictions (need not be FIFO, message loss possible).

- Histories used for semantics, specification and reasoning
- correspondence between global and local histories, both ways
- parallel composition from local history invariants
- extension of Hoare logic with send/receive statements
- avoid interference, may reason as in the sequential setting
- Bank example, showing
 - global histories may be used to exemplify the system, from which we obtain local histories, from which we get useful coding help
 - specification of local history invariants
 - verification of local history invariants from Hoare logic + verification conditions (one for each send/receive statement)
 - composition of local history invariants to a global invariant
