INF 4300 – Digital Image Analysis

SUMMARY - PART I

Fritz Albregtsen

18.11.2015

F11 18.11.15 INF 4300

Using variance estimates

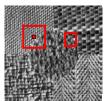

- Variance, σ^2 , is directly a measure of "roughness"
- A measure of "smoothness" is

$$R = 1 - \frac{1}{1 + \sigma^2}$$

- R is close to 0 for homogenous areas
- R tends to 1 as σ^2 , "roughness", increase

"Texture" – description of regions

- Remember: we estimate local properties (features) to be able to isolate regions which are similar in an image (segmentation), and possibly later identify these regions (classification), usually with the final goal of object description
- One can describe the "texture" of a region by:
 - smoothness, roughness, regularity, orientation...
- Problem: we want the local properties to be as "local" as possible
- Large region or window
 - Precise estimate of features
 - Imprecise estimate of location
- Small window
 - Precise estimate of location
 - Imprecise estimate of feature values

2

F11 18.11.15 INF 4300

1. order statistics discussion

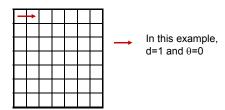

- 1. order statistics can separate two regions even if $\mu_1 = \mu_2$, as long as $\sigma^2_1 \neq \sigma^2_2$
- The statistics of a pixel (x, y) is found in a local window
- · Problems:
 - Edges around objects are exaggerated
 - Solution: use adaptive windows
 - 1. order statistics does not describe geometry or context
 - · Cannot discriminate between

- · Solution:
 - Calculate 1. order statistics with different resolutions, and obtain indirect information about 2. and higher order statistics.
 - Simply use 2. or higher order statistics.

GLCM

- Matrix element $P(i,j|d,\theta)$ in a GLCM is 2. order probability of changing from graylevel i to j when moving distance d in direction θ .
- Dimension of co-occurrence matrix is GxG (G = gray-levels in image)
- Reduce the number of gray-levels by re-quantization
- Choose a distance d and a direction θ

• Check all pixel pairs with distance d and direction θ inside the window. $Q(i,j/d,\theta)$ is the number of pixel pairs where pixel 1 in the pair has pixel value i and pixel 2 has pixel value j.

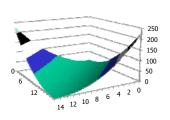

F11 18.11.15 INF 4300

GLCM features

- A number of features are available (Haralick et al., ...)
- May be seen as weight functions applied to probability matrix:
 - Weighting based on value of GLCM element
 - Example: Entropy

$$W(i,j) = -log\{P(i,j)\}$$

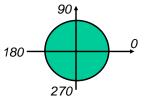

- Weighting based on position in GLCM
 - Example:
 - Inertia
 - $W(i,j) = (i-j)^2$

• You should be able to discuss which feature will discriminate between two different textures, based on the distribution of their GLCM's.

GLCM

- Usually a good idea to reduce the number of (d,θ) variations evaluated
- Simple pairwise relations:
 - $P(d,0^0) = P^t(d,180^0)$
 - $P(d,45^{\circ}) = P^{t}(d,225^{\circ})$
 - $P(d,90^{\circ}) = P^{t}(d,270^{\circ})$
 - $P(d,135^{\circ}) = P^{t}(d,315^{\circ})$

- Isotropic matrix by averaging $P(\theta)$, $\theta \in \{0^{\circ}, 45^{\circ}, 90^{\circ}, 135^{\circ}\}$
 - Beware of differences in effective window size!
- An isotropic texture is equal in all directions
- If the texture has a clear orientation, we select θ according to this.

F11 18.11.15 INF 4300

Higher order statistics

- Higher order methods include
 - Gray level runlength matrices "histograms" of graylevel run lengths in different directions (INF 5300)

F11 18.11.15 INF 4300 7 F11 18.11.15

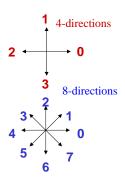

Learning goals - texture

- Understand what texture is, and the difference between first order and second order measures
- Understand the GLCM matrix, and be able to describe algorithm
- Understand how we go from an image to a GLCM feature image
 Preprocessing, choosing d and θ, selecting some features that are not too correlated
- Understand Law's texture measures and how they are built based on basic filtering operations
- There is no optimal texture features, it depends on the problem

F11 18.11.15 INF 4300

Thinning of edge in 3x3 neighborhood

- 1 Quantize the edge direction into four (or eight) directions.
- 2 If gradient magnitude G(x,y) > 0, inspect the two neighboring pixels in the given direction.
- 3 If gradient magnitude of any of these neighbors is higher than G(x,y), mark the pixel.
- 4 When all pixels have been scanned, delete or suppress the marked pixels.

Used iteratively in nonmaxima suppression.

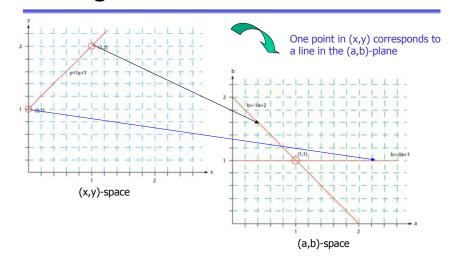

Edge-based segmentation

Two steps are needed:

- 1. Edge detection (to identify "edgels" edge pixels)
 - (Gradient, Laplacian, LoG, Canny filtering)
- 2. Edge linking linking adjacent "edgels" into edges
 - Local Processing
 - *magnitude* of the gradient
 - direction of the gradient vector
 - edges in a predefined neighborhood are linked if both magnitude and direction criteria is satisfied
 - Global Processing via Hough Transform

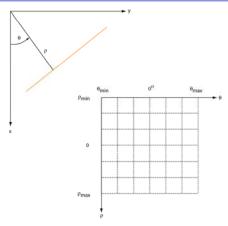

F11 18.11.15 INF 4300 10

Hough transform - basic idea

F11 18.11.15 INF 4300 11 F11 18.11.15 INF 4300 12

HT and polar representation of lines

Polar representation of lines

F11 18.11.15 INF 4300 13

Hough transform for circles

• A circle in the xy-plane is given by

$$(x-x_c)^2 + (y-y_c)^2 = r^2$$

- So we have a 3D parameter space.
- Simple 3D accumulation procedure:

set all A[
$$x_{c'}y_{c'}r$$
]=0;
for every (x , y) where g(x , y)>T
for all x_c and y_c
$$r=sqrt((x-x_c)^2+(y-y_c)^2);$$
$$A[x_{c'}y_{c'}r]=A[x_{c'}y_{c'}r]+1;$$

Better procedure ... ?

HT using the full gradient information

- Given a gradient magnitude image g(x,y) containing a line.
- Simple algorithm:

```
for all g(x_i, y_i) > T do

for all \theta do

\rho = x_i \cos \theta + y_i \sin \theta

find indexes (m,n) corresponding to (\rho, \theta) and increment A(m,n);
```

- Better algorithm if we have both
 - The gradient magnitude g(x,y)
 - And the gradient components g_x and g_y
 - So we can compute gradient direction

• The new algorithm:
for all
$$g(x, y) = \arctan\left(\frac{g_y}{g_x}\right)$$

```
for all g(x_i, y_i) > T do \rho = x_i \cos(\phi_g(x, y)) + y_i \sin(\phi_g(x, y)) find indexes (m, n) corresponding to (\rho, \phi_g(x, y)), increment A(m, n);
```

F11 18.11.15 INF 4300 14

Hough transform for ellipses

- A general ellipse in the xy-plane has 5 parameters:
 - Position of centre (x_c, y_c) , semi-axes (a,b), and orientation (θ) .
- Thus, we have a 5D parameter space.
- For large images and full parameter resolution, straight forward HT may easily overwhelm your computer!
- Reducing accumulator dimensionality:
 - Pick pixel pairs with opposite gradient directions
 - Midpoint of pair "votes" for centre of ellipse!
 - Reduces HT-accumulator from 5D to 3D.
 - Min and max distance of pixel pairs => 2b & 2a
- Reducing accumulator extent & resolution
- Using other tricks ...

F11 18.11.15 INF 4300 15 F11 18.11.15 INF 4300 16

Learning goals - HT

- Understand the basic Hough Transform, and its limitations
- Understand that the normal representation is more general
- Be able to implement line detecting HT with accumulator matrix
 - Understand how this may be improved by gradient direction information.
- Be able to implement simple HT for circles of given size, in order to find position of circular objects in image.
 - Understand how this may be improved.
- Understand simple HT to detect ellipses
 - Understand how this may be improved.
- Understand the basic random Hough transform.
- Do the exercises!

F11 18.11.15 INF 4300 17

Region growing

- Starts with a set of seeds (starting pixels)
 - Predefined seeds
 - All pixels as seeds
 - Randomly chosen seeds
- Region growing steps (bottom-up method)
 - Find starting points
 - Include neighboring pixels with similar features (graylevel, texture, color)
 - A similarity measure must be selected.

Two variants:

- 1. Select seeds from the whole range of grey levels in the image. Grow regions until all pixels in image belong to a region.
- Select seed only from objects of interest (e.g. bright structures). Grow regions only as long as the similarity criterion is fulfilled.

Σ: Edge based segmentation

- Advantages
 - An approach similar to how humans segment images.
 - Works well in images with good contrast between object and background
- Disadvantages
 - Does not work well on images with smooth transitions and low contrast
 - Sensitive to noise
 - Robust edge linking is not trivial

F11 18.11.15 INF 4300 18

Region merging techniques

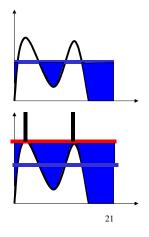

- Initialize by giving all the pixels a unique label
 - All pixels in the image are assigned to a region.
- The rest of the algorithm is as follows:
 - In some predefined order, examine the neighbor regions of all regions and decide if the predicate evaluates to true for all pairs of neighboring regions.
 - If the predicate evaluates to true for a given pair of neighboring regions then give these neighbors the same label.
 - The predicate is the similarity measure (can be defined based on e.g. region mean values or region min/max etc.).
 - Continue until no more mergings are possible.
 - Upon termination all region criteria will be satisfied.

F11 18.11.15 INF 4300 19 F11 18.11.15 INF 4300 20

Watershed segmentation (G&W:10.5)

- Look at the image as a 3D topographic surface, (x,y,intensity), with both valleys and mountains.
- Assume that there is a hole at each minimum, and that the surface is immersed into a lake.
- The water will enter through the holes at the minima and flood the surface.
- To avoid two different basins to merge, a dam is built.
- Final step: the only thing visible would be the dams.
- The connected dam boundaries correspond to the watershed lines.

F11 18.11.15 INF 4300

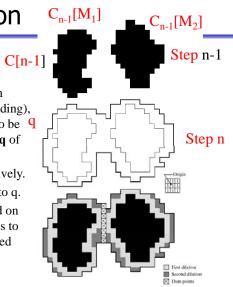

Watershed segmentation

- Can be used on images derived from:
 - The intensity image
 - Edge enhanced image
 - Distance transformed image
 - Thresholded image. From each foreground pixel, compute the distance to a background pixel.
 - Gradient of the image
- Most common: gradient image

F11 18.11.15 INF 4300 22

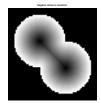

Dam construction

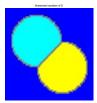

- Stage n-1: two basins forming separate connected components.
- To consider pixels for inclusion in basin k in the next step (after flooding), they must be part of T[n], and also be q part of the connected component q of T[n] that C_{n-1}[k] is included in.
- Use morphological dilation iteratively.
- Dilation of C[n-1] is constrained to q.
- The dilation can not be performed on pixels that would cause two basins to be merged (form a single connected component)

Splitting objects by watershed

- Example: Splitting touching or overlapping objects.
 - Given graylevel (or color) image
 - Perform first stage segmentation
 - (edge detection, thresholding, classification,...)
 - Now you have a labeled image, e.g. foreground / background
 - Obtain distance transform image
 - From each foreground pixel, compute distance to background.
 - Use watershed algorithm on inverse of distance image.

F11 18.11.15 INF 4300 23 F11 18.11.15 INF 4300 24

Shape representations vs. descriptors

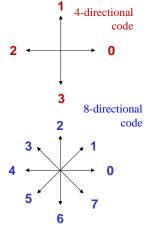

- After the segmentation of an image, its regions or edges are represented and described in a manner appropriate for further processing.
- Shape representation: the ways we store and represent the objects
 - Perimeter (and all the methods based on perimeter)
 - Interior (and all the methods ...)
- Shape descriptors: recipes for features characterizing object shape.
 - The resulting feature values should be useful for discrimination between different object types.

F11 18.11.15

INF 4300

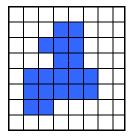

Chain codes

- Chain codes represent the boundary of a region
- Chain codes are formed by following the boundary in a given direction (e.g. clockwise) with 4-neighbors or 8-neighbors
- A code is associated with each direction
- A code is based on a starting point, often the upper leftmost point of the object

Chains

• Chains represent objects within the image or borders between an object and the background

Object pixel

- How do we define border pixels?
 - 4-neighbors
 - 8-neighbors
- In which order do we check the neighbors?
- Chains represent the object pixel, but not their spatial relationship directly.

F11 18.11.15 INF 4300 26

Start point & rotation

- The chain code depends on the starting point.
- It can be made invariant of start point by treating it as a circular/periodic sequence, and redefining the start point so that the resulting number is of minimum magnitude.
- We can also normalize for rotation by using the first difference of the chain code: (i.e., direction changes between code elements)

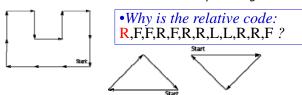

- Code: 10103322
- First difference (counterclockwise): 33133030
- To find first difference, look at the code and count counterclockwise directions.
- Treating the curve as circular, add the 3 for the first point.
- Minimum circular shift of first difference: 03033133
- This invariance is only valid if the boundary itself is invariant to rotation and scale.

F11 18.11.15 INF 4300 27 F11 18.11.15 INF 4300 28

Relative chain code

- Here, directions are defined in relation to a moving perspective.
- Example: Orders given to a blind driver ("F", "B", "L", "R").
- The directional code representing any section of the contour is relative to the directional code of the preceding section.

The absolute chain code for the triangles are 4,1,7 and 0, 5, 3.

The relative codes are 7, 7, 0. (Remember "Forward" is 2)

Invariant to rotation, as long as starting point remains the same.

Start-point invariance by "Minimum circular shift".

Note: To find the first R, we look back to the end of the contour.

F11 18.11.15

table so that 2 is forward from your

INF 4300

Sequential polygonization

- Start with any contour point as first "breakpoint".
- Step through ordered sequence of contour points.
- Using previous breakpoint as the current origin, area between contour and approximating line is:

$$A_i = A_{i-1} + \frac{1}{2} (y_i x_{i-1} - x_i y_{i-1}), \quad s_i = \sqrt{x_i^2 + y_i^2}$$

- Let previous point be new breakpoint if
 - area deviation \boldsymbol{A} per unit length \boldsymbol{s} of approximating line segment exceeds a specified tolerance, T.
- If $|A_i|/s_i < T$, i is incremented and (A_i, s_i) is recomputed.
- Otherwise, the previous point is stored as a new breakpoint, and the origin is moved to new breakpoint.
- This method is purely sequential and very fast.
- Reference: K. Wall and P.E. Danielsson, A Fast Sequential Method for Polygonal Approximation of Digital Curves, Computer Vision, Graphics, and Image Processing, vol. 28, 1984, pp. 220-227. INF 4300 31

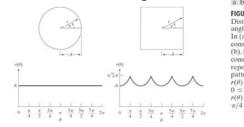

Recursive boundary splitting

- Draw straight line between contour points that are farthest apart. These two points are the initial breakpoints.
- 1. For each intermediate point:
- 2. Compute the point-to-line distance
- 3. Find the point with the greatest distance from the line.
- 4. If this distance is greater than given threshold, we have a new breakpoint.
- 5. The previous line segment is replaced by two. and 1-4 above is repeated for each of them.
- The procedure is repeated until all contour points are within the threshold distance from a corresponding line segment.
- The resulting ordered set of breakpoints is then the set of vertices of a polygon approximating the original contour
- This is probably the most frequently used polygonization.
- Since it is recursive, the procedure is fairly slow.

F11 18.11.15 INF 4300 30

Signature representations

- A signature is a 1D functional representation of a 2D boundary.
- It can be represented in several ways.
- Simple choise: radius vs. angle:

- Invariant to translation.
- Not invariant to starting point, rotation or scaling.

F11 18.11.15 INF 4300 32

Boundary segments from convex hull

- The boundary can be decomposed into segments.
 - Useful to extract information from concave parts of the objects.
- Convex hull H of set S is the smallest convex set containing S.
- The set difference H-S is called the convex deficiency D.
- If we trace the boundary and identify the points where we go in and out
 of the convex deficiency, these points can represent important border points
 characterizing the shape of the border.
- Border points are often noisy, and smoothing can be applied first.
 - Smooth the border by moving average of *k* boundary points.
 - Use polygonal approximation to boundary.
 - Simple algorithm to get convex hull from polygons.

F11 18.11.15 INF 4300

Contour representation using 1D Fourier transform

• The coordinates (x,y) of these M points are then put into a complex vector s:

$$s(k)=x(k)+iy(k), k \in [0,M-1]$$

- We choose a direction (e.g. anti-clockwise)
- We view the x-axis as the real axis and the y-axis as the imaginary one for a sequence of complex numbers.

• We have transformed the contour problem from 2D to 1D. $x = 3\ 2\ 3\ 3\ 3\ 4\ 4\ 4\ 4\ 4\ 4\ 3$ $y = 1\ 2\ 3\ 4\ 5\ 6\ 6\ 5\ 4\ 3\ 2\ 1\ 1$

7

Start

s(2) = 2 + 2i s(3) = 3 + 3is(4) = 3 + 4i

s(1) = 3 + 1i

F11 18.11.15 INF 4300 34

Fourier-coefficients from f(k)

We perform a 1D forward Fourier transform

$$a(u) = \frac{1}{M} \sum_{k=0}^{M-1} s(k) \exp\left(\frac{-2\pi i u k}{M}\right) = \frac{1}{M} \sum_{k=0}^{M-1} s(k) \left(\cos\left(\frac{2\pi u k}{M}\right) - i\sin\left(\frac{2\pi u k}{M}\right)\right), \quad u \in [0, M-1]$$

- Complex coefficients a(u) are the Fourier representation of boundary.
- *a(0)* contains the center of mass of the object.
- Exclude a(0) as a feature for object recognition.
- a(1), a(2),...,a(M-1) will describe the object in increasing detail.
- These depend on rotation, scaling and starting point of the contour.
- For object recognitions, use only the N first coefficients (a(N), N<M)
- This corresponds to setting a(k)=0, k>N-1

Fourier Symbol reconstruction

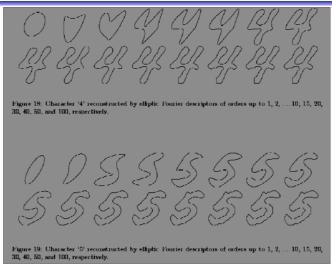

Inverse Fourier transform gives an approximation to the original contour

$$\hat{s}(k) = \sum_{k=0}^{N-1} a(u) \exp\left(\frac{2\pi i u k}{M}\right), \quad k \in [0, M-1]$$

- We have only used N features to reconstruct each component of $\hat{s}(k)$.
- The number of points in the approximation is the same (M), but the number of coefficients (features) used to reconstruct each point is smaller (N<M).
- Use an even number of descriptors.
- The first 10-16 descriptors are found to be sufficient for character description. They can be used as features for classification.
- The Fourier descriptors can be invariant to translation and rotation if the coordinate system is appropriately chosen.
- All properties of 1D Fourier transform pairs (scaling, translation, rotation) can be applied.

33

Examples from Trier et al. 1996

F11 18.11.15 INF 4300

Topologic features

- This is a group of invariant integer features
 - Invariant to position, rotation, scaling, warping
- Features based on the object skeleton
 - Number of terminations (one line from a point)
 - Number of breakpoints or corners (two lines from a point)
 - Number of branching points (three lines from a point)
 - Number of crossings (> three lines from a point)
- Region features:
 - Number of holes in the object (H)
 - Number of components (C)
 - Euler number, E = C H
 - Number of connected components number of holes

Symmetry

37

Regions with three connected components

Run Length Encoding of Objects

- Sequences of adjacent pixels are represented as "runs".
- Absolute notation of foreground in binary images:
 - Run; = ...; <row;, column;, runlength; >; ...
- Relative notation in graylevel images:
 - ...;(graylevel_i, runlength_i); ...
- This is used as a lossless compression transform.
- Relative notation in binary images:

Start value, length₁, length₂, ..., eol,

...

Start value, length₁, length₂, ..., eol,eol.

- This is also useful for representation of image bit planes.
- RLE is found in TIFF, GIF, JPEG, ..., and in fax machines.

F11 18.11.15 INF 4300 38

Projections

• 1D horizontal projection of the region:

$$p_h(x) = \sum_{y} f(x, y)$$

• 1D vertical projection of the region:

$$p_{v}(y) = \sum_{x} f(x, y)$$

- Can be made scale independent by using a fixed number of bins and normalizing the histograms.
- Radial projection in reference to centroid -> "signature".

F11 18.11.15 INF 4300 39 F11 18.11.15 INF 4300 40

Moments

- Borrows ideas from physics and statistics.
- For a given continuous intensity distribution g(x, y) we define moments m_{pq} by

$$m_{pq} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x^p y^q g(x, y) dx dy$$

• For sampled (and bounded) intensity distributions f (x, y)

$$m_{pq} = \sum_{x} \sum_{y} x^{p} y^{q} f(x, y)$$

- A moment m_{pq} is of *order* p + q.
- This moment is NOT invariant to position of object!

F11 18.11.15 INF 4300 41

Object orientation - I

- Orientation is defined as the angle, relative to the X-axis, of an axis through the centre of mass that gives the lowest moment of inertia.
- Orientation θ relative to X-axis found by minimizing:

$$I(\theta) = \sum_{\alpha} \sum_{\alpha} \beta^2 f(\alpha, \beta)$$

where the rotated coordinates are given by

$$\alpha = x \cos \theta + y \sin \theta$$
, $\beta = -x \sin \theta + y \cos \theta$

 The second order central moment of the object around the α-axis, expressed in terms of x, y, and the orientation angle θ of the object:

$$I(\theta) = \sum_{x} \sum_{y} [y \cos \theta - x \sin \theta]^2 f(x, y)$$

- \bullet $\,$ We take the derivative of this expression with respect to the angle θ
- Set derivative equal to zero, and find a simple expression for θ :

Central moments

· These are position invariant moments:

$$\mu_{p,q} = \sum_{x} \sum_{y} (x - \overline{x})^p (y - \overline{y})^q f(x, y)$$

where

$$\bar{x} = \frac{m_{10}}{m_{00}}, \quad \bar{y} = \frac{m_{01}}{m_{00}}$$

• The total mass and the center of mass are given by

$$\mu_{00} = \sum_{x} \sum_{y} f(x, y), \quad \mu_{10} = \mu_{01} = 0$$

- This corresponds to computing ordinary moments after having translated the object so that center of mass is in origo.
- Central moments are independent of position, but are not scaling or rotation invariant.
- What is μ₀₀ for a binary object?

F11 18.11.15 INF 4300

42

Object orientation - II

• Second order central moment around the α-axis:

$$I(\theta) = \sum_{x} \sum_{y} [y \cos \theta - x \sin \theta]^{2} f(x, y)$$

• Derivative w.r.t. $\Theta = 0 =>$

$$\begin{split} \frac{\partial}{\partial \theta} I(\theta) &= \sum_{x} \sum_{y} 2f(x, y) \left[y \cos \theta - x \sin \theta \right] \left[-y \sin \theta - x \cos \theta \right] = 0 \\ & \downarrow \\ & \sum_{x} \sum_{y} 2f(x, y) \left[xy \left(\cos^{2} \theta - \sin^{2} \theta \right) \right] = \sum_{x} \sum_{y} 2f(x, y) \left[x^{2} - y^{2} \right] \sin \theta \cos \theta \\ & \downarrow \\ 2\mu_{11} \left(\cos^{2} \theta - \sin^{2} \theta \right) = 2(\mu_{20} - \mu_{02}) \sin \theta \cos \theta \\ & \downarrow \\ \frac{2\mu_{11}}{(\mu_{20} - \mu_{02})} = \frac{2\sin \theta \cos \theta}{(\cos^{2} \theta - \sin^{2} \theta)} = \frac{2\tan \theta}{1 - \tan^{2} \theta} = \tan(2\theta) \end{split}$$

• So the object orientation is given by:

$$\theta = \frac{1}{2} \tan^{-1} \left[\frac{2\mu_{11}}{(\mu_{20} - \mu_{02})} \right], \quad \text{where } \theta \in \left[0, \frac{\pi}{2} \right] \text{if } \mu_{11} > 0, \ \theta \in \left[\frac{\pi}{2}, \pi \right] \text{if } \mu_{11} < 0$$

Bounding box - again

- Image-oriented bounding box:
 - The smallest rectangle around the object, having sides parallell to the edges of the image.
 - Found by searching for min and max x and y within the object (xmin, ymin, xmax, ymax)

- Smalles rectangle around the object, having one side parallell to the orientation of the object (θ) .
- The transformation

 $\alpha = x \cos \theta + y \sin \theta$, $\beta = y \cos \theta - x \sin \theta$

is applied to all pixels in the object (or its boundary).

– Then search for α_{min} , β_{min} , α_{max} , β_{max}

F11 18.11.15

INF 4300

What if we want scale-invariance?

• Changing the scale of f(x,y) by (α,β) gives a new image:

$$f'(x, y) = f(x/\alpha, y/\beta)$$

The transformed central moments

$$\mu'_{pq} = \alpha^{1+p} \beta^{1+q} \mu_{pq}$$

 If α=β, scale-invariant central moments are given by the normalization:

$$\eta_{pq} = \frac{\mu_{pq}}{(\mu_{00})^{\gamma}}, \quad \gamma = \frac{p+q}{2} + 1, \quad p+q \ge 2$$

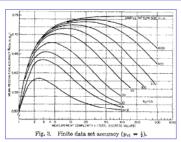

F11 18.11.15 INF 4300 46

Moments as shape features

- The central moments are seldom used directly as shape descriptors.
- Major and minor axis are useful shape descriptors.
- Object orientation is normally not used directly, but to estimate rotation.
- The set of 7 Hu moments can be used as shape features. (Start with the first four, as the last half are often zero for simple objects).

The "curse-of-dimensionality"

- Also called "peaking phenomenon".
- For a finite training sample size, the correct classification rate initially increases when adding new features, attains a maximum and then begins to decrease.
- The implication is that:
- For a high measurement complexity, we will need large amounts of training data in order to attain the best classification performance.
- => 5-10 samples per feature per class.

Correct classification rate as function of feature dimensionality, for different amounts of training data. Equal prior probabilities of the two classes is assumed.

Illustration from G.F. Hughes (1968).
