

Kap. 12

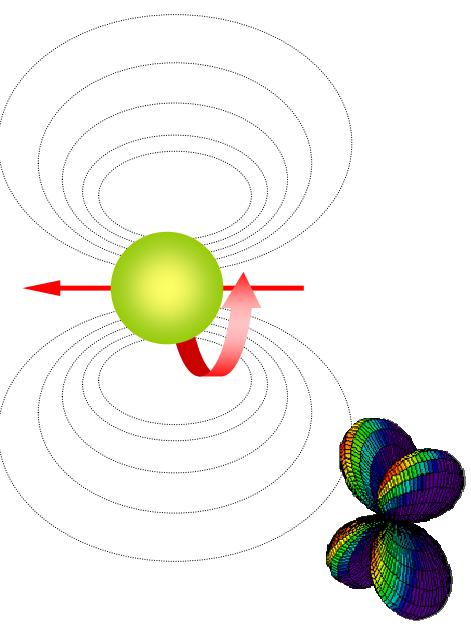

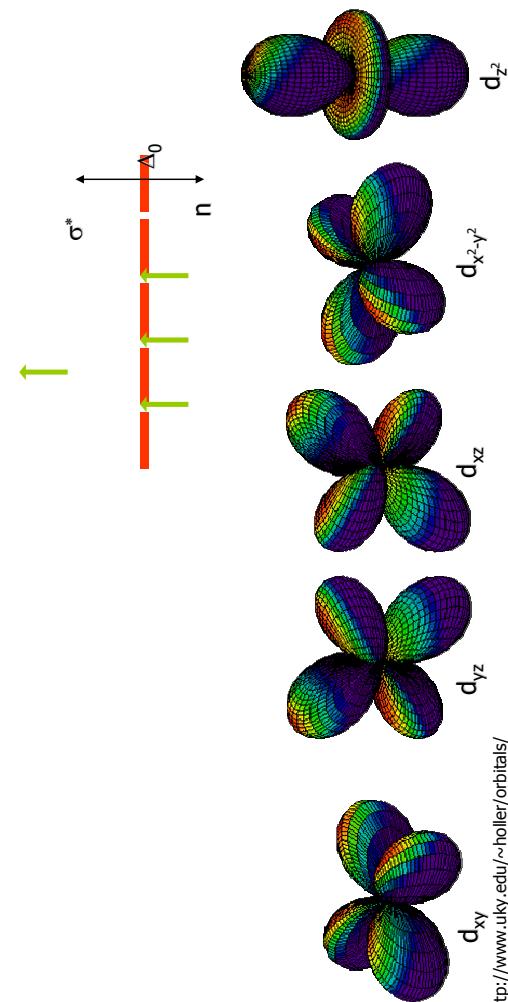

Magnetic solids

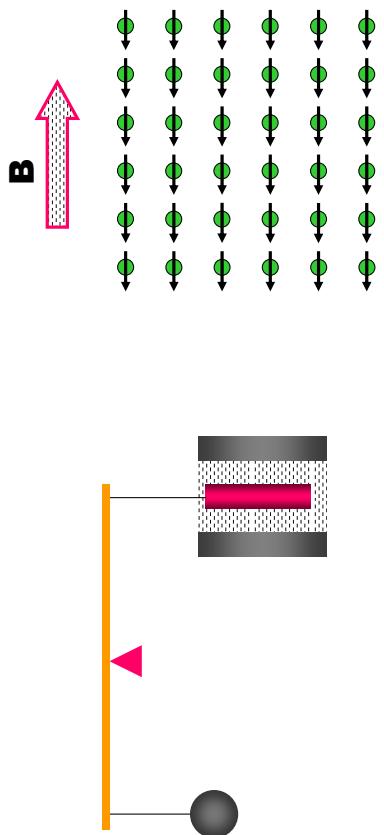

What is magnetism?

What is magnetism?

Cr	Mn	Fe	Co	Ni
----	----	----	----	----

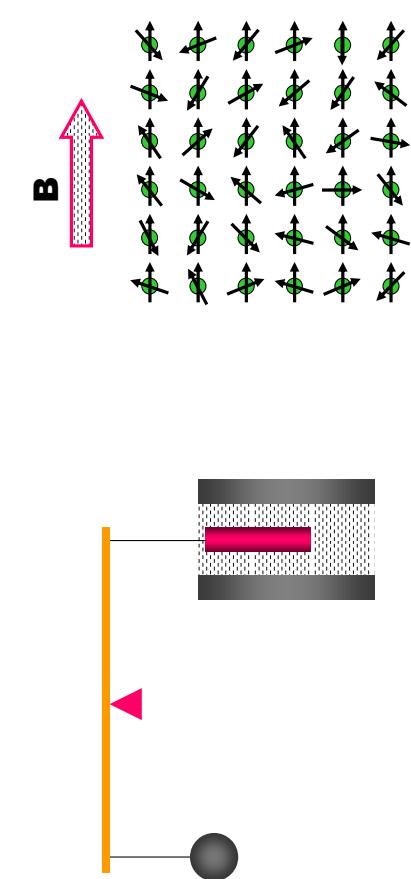

Diamagnetism

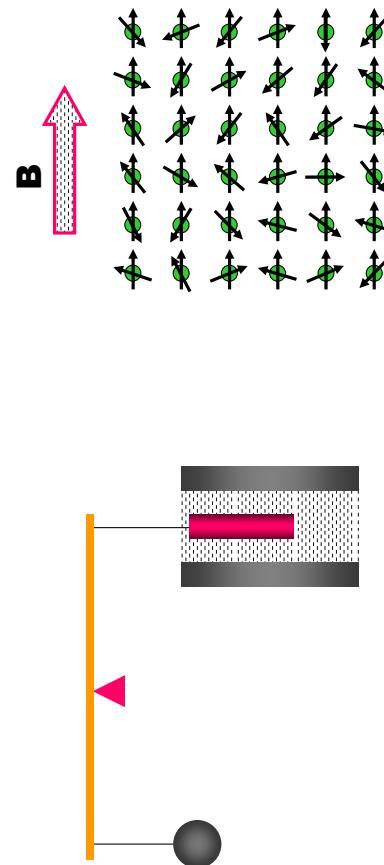

Diamagnetism occurs in materials with no unpaired electrons. Al_2O_3 , MgO etc.

Paramagnetism

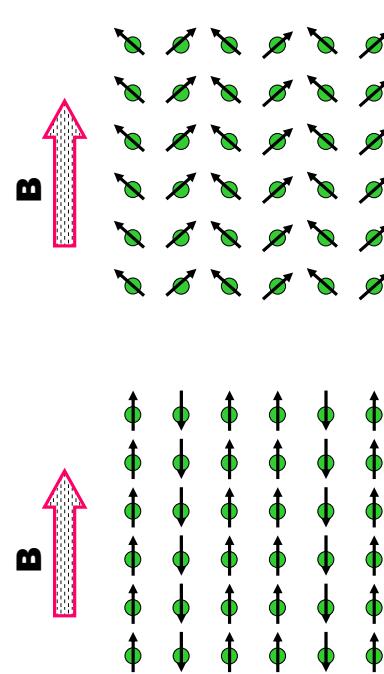

Paramagnetism occurs in materials with unpaired electrons but insufficient long range interaction between their magnetic moment. Typical phenomena at high temperatures.

Ferromagnetism

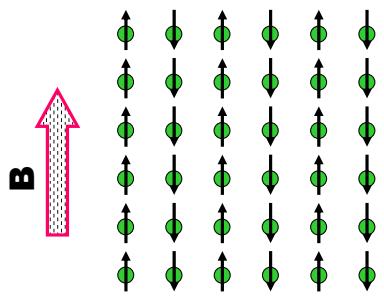

Ferromagnetism occurs in materials that has an exchange mechanism which ensures parallel orientation between the magnetic moments.

Ferri magnetism

Ferri magnetism occurs in materials that has an exchange mechanism which ensures a net orientation between the magnetic moments.

Anti-ferro magnetism

Anti ferromagnetism occurs in materials that has an exchange mechanism which ensures anti-parallel orientation between the magnetic moments.

H

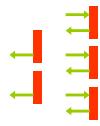

M

$$M \neq \chi H$$

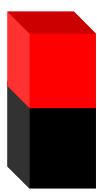

Magnetic susceptibility

$\chi < 0$: Diamagnetic
 $0 < \chi < 1$: Paramagnetic
 $\chi > 1$: Ferromagnetic

What to measure?

H

M

$$M = \chi H$$

Magnetic susceptibility

$\chi < 0$: Diamagnetic
 $0 < \chi < 1$: Paramagnetic
 $\chi > 1$: Ferromagnetic

What to measure?

Paramagnetic

$$\chi = \frac{C}{T - \theta}$$

What to measure?

Hard
Hard to magnetize and demagnetize
Very large remanence
Can be made into permanent magnets
High coercivity

Soft
Easy to magnetize and demagnetize
Minimal remanence
Low coercivity

Weak magnetic materials

Diamagnetic materials: No magnetic dipoles in the material. The material responds to external magnetic fields according to Lenz's Law.

Paramagnetic materials: The magnetic moment of the material is dependent on the quantum numbers S , L , J . The magnetic moment for transition materials can be approximated by its spin-only angular momenta:

$$m = g_J [S(S+1)]^{1/2} \mu_B$$

where: $g_J = 2$

$S = \text{number of unpaired electrons} * \frac{1}{2}$

$\mu_B = \text{Bohr magneton, magnetic moment of one electron}$

Table 12.2 The magnetic properties of the 3d transition metal ions

Ion	Configuration ^a	S	Magnetic dipole moment ^b	
			calc.	meas.
Sc ³⁺ , Ti ⁴⁺ , V ⁵⁺	d ⁰	0	0	Dia. ^c
Ti ³⁺ , V ⁴⁺	d ¹	1/2	1.73	1.7-1.8
Ti ²⁺ , V ³⁺	d ²	1	2.83	2.8-2.9
Cr ²⁺ , Mn ³⁺ , V ²⁺	d ³	3/2	3.87	3.7-4.0
Cr ³⁺ , Mn ⁴⁺ , V ¹⁺	d ⁴	2	4.9	4.8-5.0
Mn ²⁺ , Fe ³⁺	d ⁵	5/2	5.92	5.7-6.1
Co ³⁺ , Fe ²⁺	d ⁶	2	4.9	5.1-5.7
Co ²⁺	d ⁷	1	3.87	4.3-5.2
Ni ²⁺	d ⁸	1	2.83	2.8-3.5
Cu ²⁺ , Zn ²⁺	d ⁹	1/2	1.73	1.7-2.2
Cu ⁺ , Zn ¹⁺	d ¹⁰	0	0	Dia. ^c

^a The configuration of the 3d transition metals are given in Section 5.1.2.

^b Units: Bohr magnetons; calc., calculated from Equation (12.9) in text; meas., measured value.

^c Diamagnetic.

Ferromagnetic materials

Ferromagnetic materials are claimed to have an internal magnetic field.

Ferromagnetic materials, Exchange energy

The exchange energy, j , favours parallel spin as far apart as possible. \rightarrow Hunds rule

Chemical bonding favours pairing of electrons, giving no magnetic moment.

Ferromagnetic materials can be obtained when the electrons are so far apart that they can be parallel (viz. a weak bond), but still so close that they can interact magnetically.

This gives in general weak bonding.

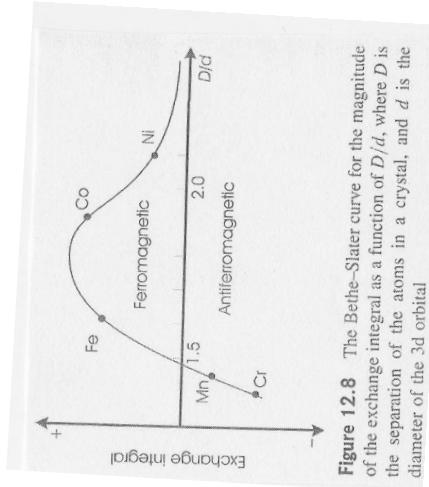

Figure 12.8 The Bethe-Slater curve for the magnitude of the exchange integral as a function of D/d , where D is the separation of the atoms in a crystal, and d is the diameter of the 3d orbital

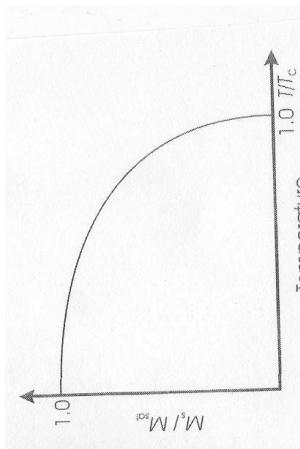

Figure 12.7 Variation of the relative spontaneous magnetisation, $M_s/M_{s\text{sat}}$, as a function of relative temperature, T/T_c . When $T = 0$ the magnetisation is equal to the saturation magnetisation, $M_{s\text{sat}}$. When $T = T_c$, the Curie temperature, the spontaneous magnetisation is zero

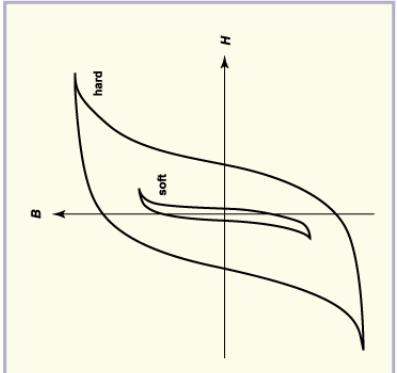

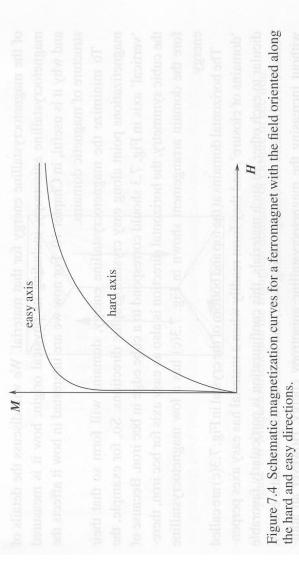

Table 12.3 Ferromagnetic and antiferromagnetic compounds

Ferromagnetic compound	T_c K	Antiferromagnetic compound	T_N K
Fe	1043	Cr	310
Co	1388	α -Mn	100
Ni	627	α -Fe ₂ O ₃	950
Gd	293	CuF ₂	69
Tb	220-230	MnF ₂	67
Dy	87-176	CoCO ₃	18
Cr ₂ O ₃	386	NiO	523
SmCo ₅	973	CoO	293
Nd ₂ Fe ₁₄ B	573	FeO	198
		MnO	1116
		K ₂ NiF ₄	97
		LaFeO ₃	750

Note: T_c : Curie temperature; T_N : Neel temperature.

Soft and hard magnets **Easy and hard axis**

Anti-ferromagnetic Superexchange

The figure shows two sets of hysteresis loops for a ferromagnetic material. The left set, labeled 'HARD', has the magnetic field H oriented along the b -axis (body diagonal). It features a large loop with a small remanence loop inside. The right set, labeled 'EASY', has H oriented along the a -axis (face diagonal). It also features a large loop with a smaller remanence loop inside.

Ferrimagnetic materials, Doubleexchange

Figure 12.10 Double exchange, possible only with ferromagnetic alignment of spins on cations

Doubleexchange occurs when electrons can jump between using an intermediate oxygen as bridge. Both electrons jump simultaneously. This produces parallel spin on the metal atoms.

This mechanism is frequent in inverted etc.) giving ferrimagnetic materials.

Superexchange occurs when an intermittent atom (Oxygen) transfers orbital information so that the metallic neighbours must be anti-parallel in orbital moment.

Without this exchange the material would be paramagnetic.

Typical mechanism for anti-ferromagnetic oxides with NaCl-type structure.

T_N increases with covalency: MnO, FeO, CoO, NiO and is dependent on orbital overlap, viz. M-O-M angle

Domains

Ferromagnetic material produce a microstructure of magnetic domains "Weiss domains". These reduce the reduce the magnetostatic energy.

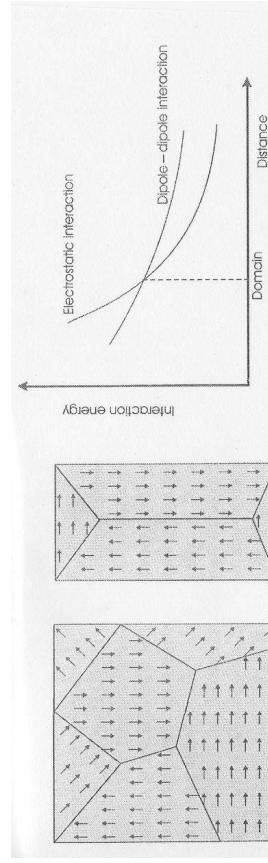

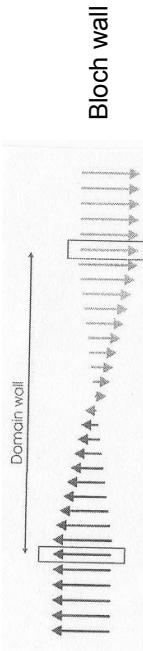

Figure 12.12 (a) Representation of Weiss domains; the magnetic dipoles are represented by arrows; (b) Domain closure; and (c) graph of interaction energy as a function of distance. The dipole-dipole interactions in the solid tend to produce antiparallel alignment of magnetic dipoles, and the electrostatics interactions a parallel alignment of magnetic dipoles. The domain size is a reflection of the point where these interactions balance

using an intermediate oxygen as bridge. Both electrons jump simultaneously. This produces parallel spin on the metal atoms.

Domains

Pauli paramagnetism

$$C \quad \text{Paramagnetic metals do not show a Curie Weiss relationship.} \quad \chi = \frac{C}{T}$$

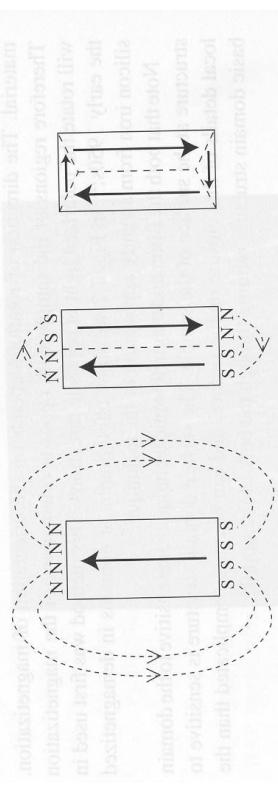

Figure 7.3 Reduction of the magnetostatic energy by domain formation in a ferromagnet.

By applying an external field the density of states for the up and down spin states shifts differently. The susceptibility becomes dependent on the applied field, but not temperature.

$$\chi = \frac{\mu_0 \mu_B^2 N}{E_F}$$

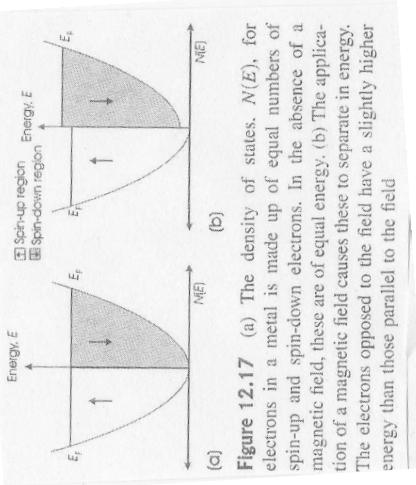

Figure 12.17 (a) The density of states, $N(E)$, for electrons in a metal is made up of equal numbers of spin-up and spin-down electrons. In the absence of a magnetic field, these are of equal energy. (b) The application of a magnetic field causes these to separate in energy. The electrons opposed to the field have a slightly higher energy than those parallel to the field

Superparamagnetism

When particles of a magnetic solid are below the domain size, the electrostatic interactions dominate. The magnetic dipoles tend to align parallel to each other and a superparamagnetic state results.

Domain closure in thin films

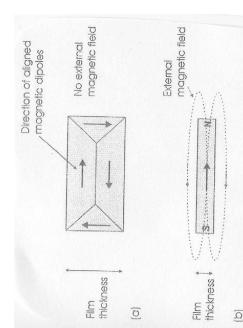

Figure 12.19 (a) Domain closure in a bulk film prevents magnetic flux from escaping. (b) A film less than a domain wall has magnetic dipoles aligned, so the flux escapes longitudinally; acicular crystals in magnetic recording media are ideally in this form. (c) A thin film of the order of one atomic thickness has elementary dipoles aligned perpendicular to the film, allowing flux to escape normal to the film
