# Siloxenes

Wöhler 1863

R. NESPER ETH ZÜRICH & COLLEGIUM HELVETICUM

"Das Silicon (= Siloxen) ist lebhaft orangegelb; es besteht aus durchscheinenden gelben Blättchen[...]. Es ist unlöslich in Wasser, in Alkohol, in Kieselchlorid, in Phosphorchlorid, in Schwefelkohlenstoff. Beim Erwärmen wird es vorübergehend tiefer orangegelb. Stärker erhitzt entzündet es sich und verbrennt mit schwacher Verpuffung und Funkensprühen unter Zurücklassung von Kieselsäure, die durch amorphes Silicium braungefärbt ist. Ohne Luftzutritt erhitzt, entwickelt es Wasserstoffgas und hinterläßt ein Gemenge von Kieselsäure und amorphem Silicium in Gestalt glänzender, schwarzbrauner Blättchen. Erst nach vollem Glühen hört die Wasserstoffentwicklung auf. War es mit einer nicht ganz konzentrierten Säure bereitet, so enthält es die weiter unten beschriebene Verbindung beigemengt; es ist dann heller an Farbe und zeigt beim Erhitzen auch in einer Röhre eine Art Verpuffung, unter gleichzeitiger Entwicklung von selbstentzündlichen Kieselwasserstoffgas. Diese Zersetzung des Silicons in der Wärme beginnt schon bei 100 °C[...]."

Eidgenössische Technische Hochschule Zürich  
Swiss Federal Institute of Technology Zurich

Sehr merkwürdig ist sein Verhalten im Licht. Im Dunkeln bleibt es, selbst im feuchten Zustand, ganz unverändert; im zerstreuten Licht wird es zunehmend blasser und im direkten Sonnenlicht wird es nach kurzer Zeit vollkommen weiß, und zwar unter Entwicklung von Wasserstoffgas. Stellt man es unter Wasser in den Sonnenschein, so fängt es augenblicklich an Wasserstoffgas zu entwickeln, was gleich einer Gährungserscheinung fort dauert, bis es ganz weiß geworden ist [...]. Das Silicon wird weder von Chlor noch rauchender Salpetersäure oder von konzentrierte Schwefelsäure angegriffen, selbst nicht beim Erhitzen damit. Flußsäure erhitzt sich damit; es erhebt sich darin zugleich an die Oberfläche, wird allmählich heller, zuletzt weiß und verschwindet endlich ganz [...]".

## Ionic Liquids

### Charakteristic properties:

- low vapour pressure
- thermischal stability
- elektric conductivity
- Phasenseparation from products
- high thermal capacity
- non burning

These liquids are – in contrast to salt melts – not corrosive and thus are used to replace ordinary organic solvents

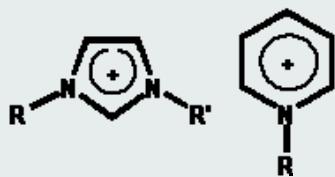

### fields of applications

- head carrier
- Elektrolyte
- Analytics
- separator
- Membran etechniques

P. Wasserscheid und W. Keim.  
Angew. Chem. 2000, 112, 3926-3945.

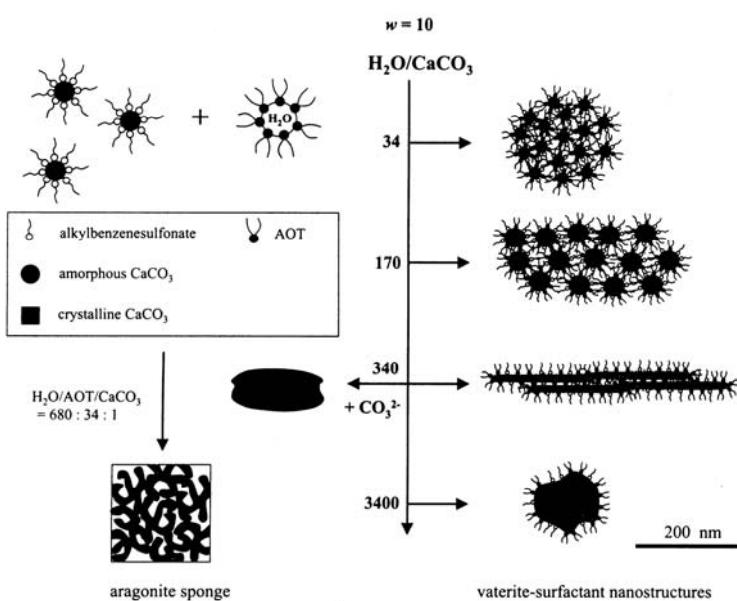

Fig. 8. General scheme showing experimental conditions and types of hybrid surfactant-vaterite nanostructures synthesized by microemulsion-mediated phase transformation of surfactant-stabilized ACC nanoparticles. Reagents are shown top/middle left. Nanostructures produced at  $w=10$  using different water droplet/amorphous CaCO<sub>3</sub> nanoparticle ratios are shown on the right. The aggregated structures are drawn approximately to scale (bar = 200 nm).

02.11.2006

## Loaded Micelles and Dendrimers

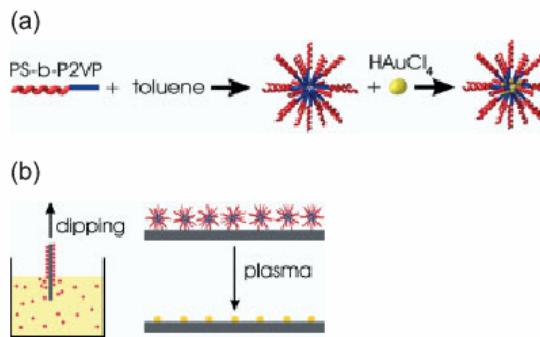

Fig. 1. a) Sketch of the formation of reverse micelles within PS-P2VP diblock copolymer solutions. The core of the micelle can be loaded with a metal precursor (e.g., HAuCl<sub>4</sub>). b) The reverse micelles in solution are transferred onto substrates by dip coating. The polymer is removed and, simultaneously, the metal salt is reduced by applying either an oxygen plasma followed by a hydrogen plasma or by a single hydrogen plasma step (more details are given below).

02.11.2006

Nanochemistry UIO

33

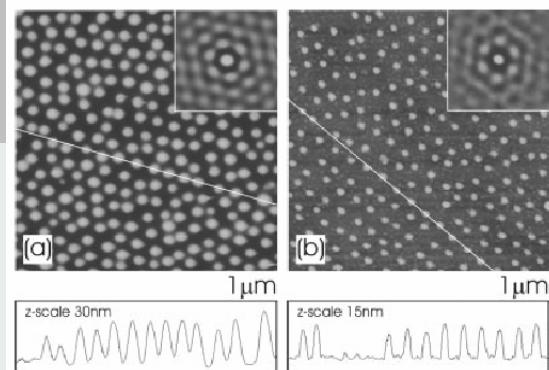

Fig. 2. Gold-loaded micelles on a silicon substrate before ((a), z-scale 30 nm) and after ((b), z-scale 15 nm) removal of the polymer matrix. Clearly, the order of the resulting nanoparticles reflects the order of the original micellar array. Local order is reasonably good as proven by the autocorrelation functions in the insets. The bottom panels show the results of line scans measured along the white lines shown.

## Loaded Micelles and Dendrimers

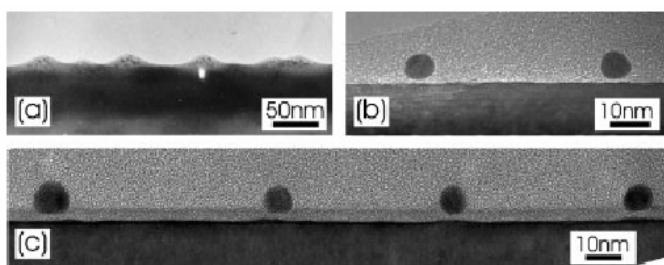

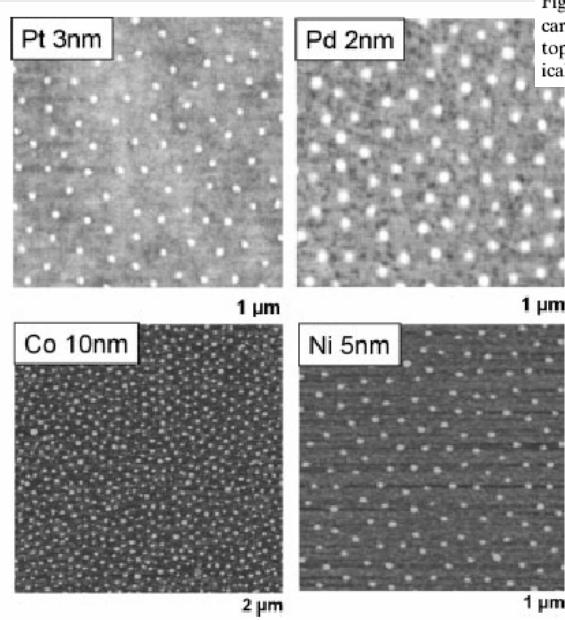

Fig. 10. TEM cross-section images of Au-salt-loaded micelles deposited onto a carbon-coated copper grid (a) and of the final array of Au nanodots prepared on top of a sapphire substrate (b) and on silicon (c), demonstrating the nearly spherical shape of the resulting particles.

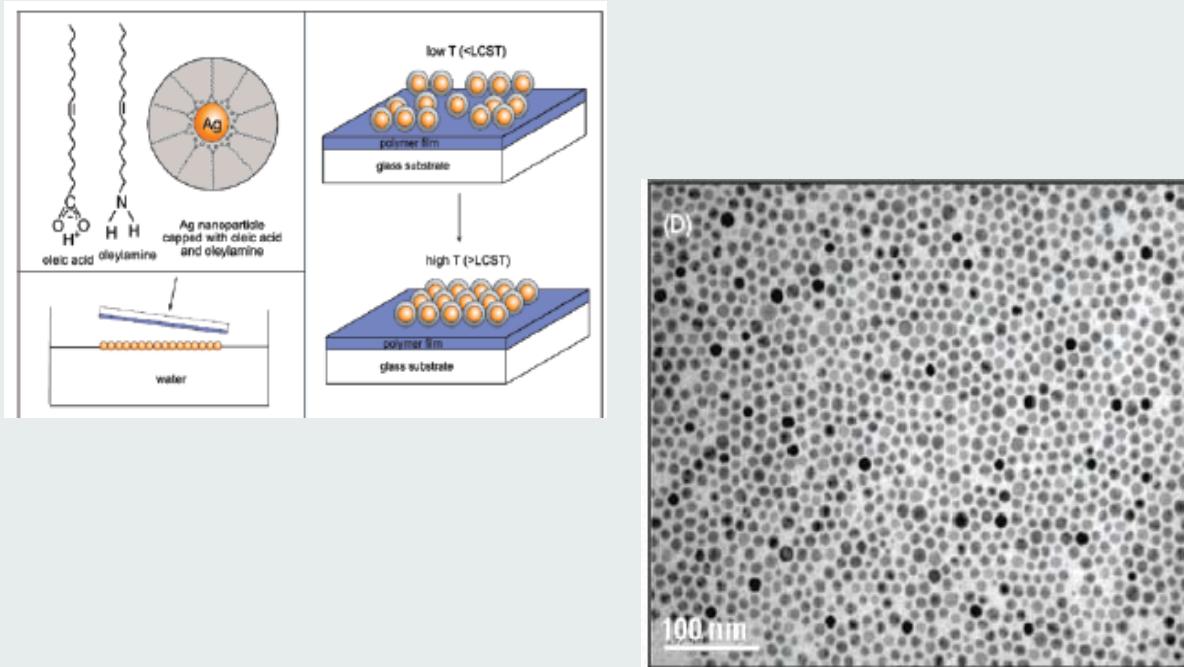

Fig. 11. AFM images of nanoparticles prepared from different elements. The universality of the micellar approach allows a wide variety of metallic, magnetic, or oxide particles to be prepared.
