## LP. Kap. 17: Interior-point methods

- the simplex algorithm moves along the boundary of the polyhedron $P$ of feasible solutions
- an alternative is interior-point methods
- they find a path in the interior of $P$, from a starting point to an optimal solution
- for large-scale problems interior-point methods are usually faster
- we consider the main idea in these methods

simplex method
interior point methods

## 1. The barrier problem

Consider the LP problem

$$
\begin{array}{ll}
\max & c^{\top} x \\
\text { s.t. } & \\
& A x \leq b \\
& x \geq 0
\end{array}
$$

and its dual

$$
\begin{array}{ll}
\min & b^{T} y \\
\text { s.t. } \\
& \\
& A^{T} y
\end{array}
$$

Introduce slack variables $w$ in the primal and (negative) slack $z$ in the dual, which gives

Primal (P):

$$
\begin{array}{ll}
\max & c^{T} x \\
\text { s.t. } \\
& A x+\quad w=b, \\
& x, w \geq 0
\end{array}
$$

Dual (D):

$$
\begin{aligned}
& \min b^{T} y \\
& \text { s.t. } \\
& \\
& \\
&
\end{aligned} A^{T} y-z=c, ~=y, z \geq 0
$$

- We want to rewrite the problems such that we eliminate the constraints $x, w \geq 0$ og $y, z \geq 0$, but still avoid negative values (and 0 ) on the variables!!
- This is achieved by a logarithmic barrier function, and we get the following modified primal problem

The barrier problem:

$$
\begin{array}{ll} 
& \max \\
\left(P_{\mu}\right): & c^{T} x+\mu \sum_{j} \log x_{j}+\mu \sum_{i} \log w_{i} \\
& A x+w=b
\end{array}
$$

- $\left(P_{\mu}\right)$ is not equivalent to the original problem (P), but it is an approximation
- it contains a parameter $\mu>0$.
- remember: $x_{j} \rightarrow 0^{+}$implies that $\log x_{j} \rightarrow-\infty$.
- $\left(\mathrm{P}_{\mu}\right)$ is a nonlinear optimization problem
- interpretation/geometry: see Figure 17.1 in Vanderbei: level curves for $f_{\mu}$, polyhedron $P$, central path when $\mu \rightarrow 0$.
- Goal: shall see that $\left(\mathrm{P}_{\mu}\right)$ has a unique optimal solution $x(\mu)$ for each $\mu>0$, and that $x(\mu) \rightarrow x^{*}$ when $\mu \rightarrow 0^{+}$, where $x^{*}$ is the unique optimal solution of $(P)$. (Note: $w$ is uniquely determined by $x$ )

Plots of $\mu \log x$ for various values of $\mu$ :

## 2. Lagrange multiplier

From (for instance) T. Lindstrøm, "Optimering av funksjoner av flee variable", MAT1110, multivariable calculus) we have the following Lagrange multiplier rule:

Theorem Assume $U \subseteq \mathbb{R}^{n}$ is open, and that $f, g_{i}: U \rightarrow \mathbb{R}$ are functions with continuous partial derivatives ( $i \leq m$ ), and let $b_{1}, \ldots, b_{m} \in \mathbb{R}$. Assume that $x^{*}$ is a local maximum (or minimum) for $f$ on the set

$$
S=\left\{x \in \mathbb{R}^{n}: g_{i}(x)=0(i \leq m)\right\}
$$

and that $\nabla g_{1}\left(x^{*}\right), \ldots, \nabla g_{m}\left(x^{*}\right)$ are linearly independent. Then there are constants $\lambda_{1}, \ldots, \lambda_{m}$ such that

$$
(*) \quad \nabla f\left(x^{*}\right)=\sum_{i=1}^{m} \lambda_{i} \nabla g_{i}\left(x^{*}\right) .
$$

- $\lambda_{i}$ 's are called Lagrange multipliers
- This is a necessary optimality condition and leads to $n+m$ equations for finding $x$ and $\lambda$ ( $n+m$ variables).

This can also be expressed by the Lagrange function:

$$
\begin{gathered}
L(x, y)=f(x)-\sum_{i=1}^{m} y_{i} g_{i}(x) . \\
\nabla_{x} L\left(x^{*}, y\right)=0
\end{gathered} \quad \nabla f=\sum_{i=1}^{m} t_{i} \nabla g_{i}=0
$$

while the constraints $g_{i}\left(x^{*}\right)=0(i \leq m)$ become (where $\left.y=\lambda\right)$

$$
\nabla_{y} L\left(x^{*}, y\right)=0 .
$$

These equations are called the first-order optimality conditions and a solution $x^{*}$ is called a critical point.
Are these conditions also sufficient for optimality?
Consider the Hessian matrix

$$
H_{f}(x)=\left[\frac{\partial^{2} f(x)}{\partial x_{i} \partial x_{j}}\right] \in \mathbb{R}^{n \times n}
$$

Note: $f(x)=o\left(g(x)\right.$ when $x \rightarrow 0$ means $\lim _{x \rightarrow 0} f(x) / g(x)=0$

Theorem 17.1 Let the $g_{i}$ 's be linear functions, and assume $x^{*}$ is a critical point. Then $x^{*}$ is a local maximum if

$$
z^{T} H_{f}\left(x^{*}\right) z<0
$$

for each $z \neq 0$ satisfying $z^{T} \nabla g_{i}\left(x^{*}\right)=0(i \leq m)$.

$$
\begin{aligned}
& \text { Proof: Second order Taylor formula gives } \\
& \qquad f\left(x^{*}+z\right)=f\left(x^{*}\right)+\overbrace{\nabla f\left(x^{*}\right)^{T} z+(1 / 2) z^{T}}^{\text {In }} H_{f}\left(x^{*}\right) z+o\left(\|z\|^{2}\right)
\end{aligned}
$$

where $z$ is a perturbation from the point $x^{*}$. To preserve feasibility $z$ must be chosen such that $x^{*}+z$ satisfies the constraints, ie., $z^{T} \nabla g_{i}\left(x^{*}\right)=0(i \leq m)$. But, since $x^{*}$ is a critical point

$$
\nabla f\left(x^{*}\right)^{T} z=\left(\sum_{i=1}^{m} \lambda_{i} \nabla g_{i}\left(x^{*}\right)\right)^{T} z=0
$$

so the assumption ( $z^{T} H_{f}\left(x^{*}\right) z<0$ for ...) and Taylor's formula give that $f\left(x^{*}+z\right) \leq f\left(x^{*}\right)$, so $x^{*}$ is a local maximum.

$$
\begin{aligned}
g:(x)= & 0 \\
\text { Note: } & \text { f }^{\top} H_{f}(x) z<0 \\
& \text { for all } x \in R^{7} \text { thee } \\
& x^{x} \text { is a global maximum } \\
& \text { unique }
\end{aligned}
$$

Similar situation in $\mathbb{R}$

$$
\begin{aligned}
& f^{\prime}\left(x^{7}\right)=0 \\
& f^{\prime \prime}\left(x^{\prime}\right)<0
\end{aligned}
$$

## 3. Lagrange applied to the barrier problem

The barrier problem $\left(\mathrm{P}_{\mu}\right)$ :

$$
\begin{array}{ll}
\max & c^{T} x+\mu \sum_{j} \log x_{j}+\mu \sum_{i} \log w_{i} \\
\text { s.t. } & \\
& A x+w=b
\end{array}
$$

Introduce the Lagrange function

$$
L(x, w, y)=c^{T} x+\mu \sum_{j} \log x_{j}+\mu \sum_{i} \log w_{i}+y^{T}(b-A x-w)
$$

First-order optimality condition becomes

$$
\begin{array}{ll}
\frac{\partial L}{\partial x_{j}}=c_{j}+\mu \frac{1}{x_{j}}-\sum_{i} y_{i} a_{i j}=0 & (j \leq n) \\
\frac{\partial L}{\partial w_{i}}=\mu \frac{1}{w_{i}}-y_{i}=0 & (i \leq m) \\
\frac{\partial L}{\partial y_{i}}=b_{i}-\sum_{j} a_{i j} x_{j}-w_{i}=0 & (i \leq m)
\end{array}
$$

Notation: write $X$ for the diagonal matrix with the vector $x$ on the diagonal. $e$ is the vector with only 1's.

Then first order optimality conditions become, in matrix form:

$$
\begin{aligned}
A^{T} y-\mu X^{-1} e & =c \\
y & =\mu W^{-1} e \\
A x+w & =b
\end{aligned}
$$

Introduce $z=\mu X^{-1} e$ and we obtain (1.OPT)

$$
\begin{aligned}
A x+w & =b \\
A^{T} y-z & =c \\
z & =\mu X^{-1} e \\
y & =\mu W^{-1} e
\end{aligned}
$$

We had:

$$
\begin{aligned}
A x+w & =b \\
A^{T} y-z & =c \\
z & =\mu X^{-1} e \\
y & =\mu W^{-1} e
\end{aligned}
$$

Multiply the third equation by $X$ and the fourth with $W$ and we get

$$
\begin{aligned}
& \begin{aligned}
A x+w & =b \\
(* *) & A^{T} y-z
\end{aligned} \\
&=c \\
& X Z e=\mu e \\
& Y W e=\mu e
\end{aligned}
$$

The last two equations say: $x_{j} z_{j}=\mu(j \leq n)$ and $y_{i} w_{i}=\mu$ ( $i \leq m$ ) which is $\mu$-complementarity (approximative complementary slack). These are nonlinear. In total we have $2(n+m)$ equations and the same number of variables.

It is quite simple:

- Interior-point methods (at least this type) consist in solving the equations $(* *)$ approximately using Newton's method for a sequence of $\mu$ 's (converging to 0 ).

4. Second order information

We show: if there is a solution of the opt. condition (**), then it must be unique! We use Theorem 17.1 and consider the barrier function $f(x, w)=c^{T} x+\mu \sum_{j} \log x_{j}+\mu \sum_{i} \log w_{i}$
First derivative:

$$
\begin{array}{ll}
\frac{\partial f}{\partial x_{j}}=c_{j}+\frac{\mu}{x_{j}} \text { fld } & (j \leq n) \\
\frac{\partial f}{\partial w_{i}}=\frac{\mu}{w_{i}} & (i \leq m)
\end{array}
$$

Second derivative:

$$
\begin{array}{ll}
\frac{\partial^{2} f}{\partial x_{j}^{2}}=-\frac{\mu}{x_{j}^{2}} & (j \leq n) \\
\frac{\partial^{2} f}{\partial w_{i}^{2}}=-\frac{\mu}{w_{i}^{2}} & (i \leq m)
\end{array}
$$

$$
\frac{\partial^{2} \downharpoonleft}{\partial x_{j} \partial \omega_{i}}=0
$$

So the Hessian matrix is a diagonal matrix with negative diagonal elements: this matrix is negative definite. Uniqueness then follows from Teorem 17.1.

$$
z^{\top} H(x, w) z<0 \quad \forall z
$$

5. Existence

Theorem 17.2 There is a solution of the barrier problem if and only if both the primal feasible region and the dual feasible region have a nonempty interior.

Proof: Shall show the "if"-part.

- Assume there is a $(\bar{x}, \bar{w})>O$ such that $A \bar{x}+\bar{w}=b$ (relative interior point in the ( $x, w$ )-space), and ( $\overline{\bar{y}}, \bar{z})>O$ with $A^{T} \bar{y}-\bar{z}=c$.
- Let $(x, w)$ be primal feasible. Then

$$
\bar{z}^{T} x+\bar{y}^{T} w=\left(A^{T} \bar{y}-c\right)^{T} x+\bar{y}^{T}(b-A x)=b^{T} \bar{y}-c^{T} x .
$$

SO

$$
c^{T} x=-\bar{z}^{T} x-\bar{y}^{T} w+b^{T} \bar{y}
$$

- The barrier function $f$ becomes

$$
\begin{array}{ll}
f(x, w) & =c^{\top} x+\mu \sum_{j} \log x_{j}+\mu \sum_{i} \log w_{i} \\
& =\sum_{j} \underbrace{\left(-\bar{z}_{j} x_{j}+\mu \log x_{j}\right)}+\sum_{i} \underbrace{\left(-\bar{y}_{i} w_{i}+\mu \log w_{i}\right)}+b^{b^{\top} \bar{y}} \\
\underbrace{}_{13 / 1}
\end{array}
$$

Behave like $h(v)=-a v+\mu \log v$ have where $a>0$

- have max in $\frac{N}{a}$
$-h(v) \rightarrow-\infty \quad$ if

$$
v \rightarrow 0 \text { or } v \rightarrow \infty
$$

$$
\text { The get }\{v: h(v) \geqslant \delta\}
$$

is bounded (and closed)

$$
\text { for any } \delta>0
$$

- The terms in each sum has the form $h(v)=-a v+\mu \log v$ where $a>0$ and $0<v<\infty$ and this function has a unique maximum in $\mu / a$ and tends to $-\infty$ as $v \rightarrow \infty$. This implies that the set $\{(x, w): f(x, w) \geq \delta\}$ is bounded for each $\delta$.
- Let now $\delta=\bar{f}=f(\bar{x}, \bar{w})$ and define the set

$$
\begin{aligned}
\bar{P}= & \{(x, w): A x+w=b, x \geq 0, w \geq 0,\} \\
& \cap\{(x, w): x>0, w>O, f(x, w) \geq \bar{f}\} .
\end{aligned}
$$

Then $\bar{P}$ is closed. Because: $\bar{P}$ is an intersection between two $f(x, w) \geqslant \bar{f}$ closed sets; the last set is closed as $f$ is continuous (that the domain $\{(x, w): x>0, w>O\}$ is not closed does not matter here.)

- Therefore $\bar{P}$ is closed and bounded, ie., compact. $\bar{P}$ is also nonempty (it contains ( $\bar{x}, \bar{w}$ )). By the extreme value theorem $f$ attains its supremum on $\bar{P}$, and therefore also on $\{(x, w): A x+w=b, x>O, w>O\}$ as desired.
$\Rightarrow$ The batnier problem has ${ }_{14 / 1}$
a solution

We then obtain (using an exercise saying that the dual has an Ex. 10.7 interior point when the primal feasible region is bounded):

Corollary 17.3 If the primal feasible region has interior points and is bounded, then for each $\mu>0$ there exists a unique solution

$$
(x(\mu), w(\mu), y(\mu), z(\mu))
$$

of ( $* *$ ).
We then get a path (curve)
$p(\mu):=\{(x(\mu), w(\mu), y(\mu), z(\mu)): \mu>0\}$ in $\mathbb{R}^{2(m+n)}$ which is called the primal-dual central path.
In the primal-dual path following method one computes a sequence $\mu^{(1)}, \mu^{(2)}, \ldots$ converging to 0 , and for each $\mu^{(k)}$ one approximately solves the nonlinear system of equations (**) using Newton's method. The corresponding sequence $p\left(\mu^{k}\right)$ will then converge towards an optimal optimal primal-dual solution. A more precise result on this convergence, and more details, are found in Chapter 18 and 19 (not syllabus).

Path following method (18.1)

Nonlinear in the unknown $\Delta^{\prime} S$
Approximation: skip nonlinear terms

$$
\begin{aligned}
A \Delta x+\Delta w & =b-A x-w \\
A^{T} \Delta y-\Delta z & =c-A^{T} y+z \\
Z \Delta x+X \Delta z & =\mu e-Z X e \\
W \Delta y+Y \Delta w & =\mu e-W Y e
\end{aligned}
$$

Linear equations that can be solved!
Corresponds to Newtons method
See chapter 18 for details

Example: A problem with $m=40$ and $n=100$. We show $\ell_{2}$-norm of the the residuals for each iteration: (primal) $\rho=b-A x-w$; (dual) $\sigma=c-A^{T} y+z$; (compl.slack.) $\gamma=z^{T} x+y^{\top} w$. We find an optimal solution.
