Converting Air Temperatures 1

- ▶ In Fahrenheit, water freezes at 32°F and boils at 212°F. It follows that the exact conversion formula is

$$C = \frac{5}{9}(F - 32).$$

- ▶ However, we would like to have a simpler approximation formula that we can convert easily in our head. Such a formula will only work well for a certain interval, and we will first consider air temperatures.
- ▶ We will explore the simpler formula

$$c = \frac{1}{2}(f - 30).$$

Converting Air Temperatures 2

- ▶ When is this formula exact? We have

$$\frac{1}{2}(F - 30) = \frac{5}{9}(F - 32)$$

$$9(F - 30) = 10(F - 32)$$

$$320 - 270 = F$$

$$F = 50,$$

so 50°F gives 10°C with both formulas.

Converting Air Temperatures 3

- ▶ If F increases by 18°F , then the exact formula increases by 10°C , while the approximation formula increases by 9°C .
- ▶ So if you are converting temperatures between $30^{\circ}\text{C} = 10^{\circ}\text{C} + 2 \cdot 10^{\circ}\text{C}$ and $-10^{\circ}\text{C} = 10^{\circ}\text{C} - 2 \cdot 10^{\circ}\text{C}$, then the approximation formula will never be more than 2°C off.

Converting Oven Temperatures 1

- ▶ However, if you are converting oven temperatures for baking, this is not a useful interval. We instead try the formula

$$c = \frac{1}{2}f.$$

- ▶ Now the fixed point is

$$\frac{1}{2}f = \frac{5}{9}(f - 32)$$

$$9f = 1098(f - 32)$$

$$320 = f,$$

so 320°F gives 160°C with both formulas.

- ▶ The same argument as above, shows that if you are converting temperatures between $60^{\circ}\text{C} = 160^{\circ}\text{C} - 10 \cdot 10^{\circ}\text{C}$ and $260^{\circ}\text{C} = 160^{\circ}\text{C} + 10 \cdot 10^{\circ}\text{C}$, the approximation formula will never be more than 10°C off.
