INNOVATION NEEDS

NEED FOR NEW STATISTICAL METHODS

HERE SITS YOUR PROJECT

- much data from different sources, (almost too much data)
- more complex data, because we measure more in depth
- necessary to discover “second order effects”
- computationally intensive procedures

Multicompare

- Assume you need to monitor, understand, compare, or predict very many dependent things, simultaneously.

For example:

- 30000 genes, to find which are causing a disease;
- 10000 financial products, to detect strange behaviours;
- 5000 clients, to find the most dangerous ones.

- We have such data and questions in many areas!

- Classical tests fail:
 - it produces too many false positives and false negatives.

Multicompare

- Recently, an explosion of new and better approaches.
 - False discovery rate
 - Multiple testing
 - Sparsity ...
- We have developed a new method and code, that takes advantage of multiple data sets (data integration)
- We have applied it to genomics.
- What shall you do?
 - understand the problem
 - understand the new method
 - apply it to a new area, for example in finance and/or
 - extend the method, so that it is more flexible to the type of test

MicroSurv

- Regression with many covariates and much less observations:
 - 10 000 covariates (x_1, \dots, x_{10000})
 - 200 cases (y)
- $p \gg n$
- Impossible to do usual (logistic, Cox) regression
- Methods to reduce the number of covariates, finding the important ones (lasso, ridge regression, variable selection ...)
- We have done cases in genomics and want to do other type of data now.
- Macro-economics? Biology? Finance?
