

Problem Set - Multinomial choice

1. Binomial. Wooldridge 15.6
2. The following output relates choice of heating system (gas central, gas room, electricity central, electricity room, heat pump) to i) operating cost (oc_) and ii) installation cost (ic_). Costs are in 1000\$.

```
. clogit choice oc_ ic_ , group(idcase)

Conditional (fixed-effects) logistic regression   Number of obs   =       4500
                                                  LR chi2(2)      =       706.51
                                                  Prob > chi2     =       0.0000
Log likelihood = -1095.2371                    Pseudo R2       =       0.2439

```

- (a) How much is the decision maker willing to pay in terms of higher installation cost for a 1\$ reduction in operating cost? Do you think this is a reasonable amount?

Suppose choice maker's i utility from alternative j is $y_{ij}^* = \alpha TC_j + a_{ij}$, where TC_j = Total cost of alternative j , which equals installation cost plus the present value of operating cost.

- (a) What is the present value of the operating cost if heating systems work from period 0 to T ?
 - (a) If heating systems never break, how can you simplify your answer in (b)?
 - (a) If you interpret the conditional logit results above using the latent utility $y_{ij}^* = \alpha TC_j + a_{ij}$, what discount rate do you estimate?
 - (a) What is the standard error on your estimate in (d)?
3. Say you have 200 observations of the choice between 3 alternatives,

y	0	1	2
n	100	40	60

Assume that the choice between the alternatives is generated from a latent variable $y_i^* = \alpha + \varepsilon_i$, and that the choices are ordered. What does this mean about how individuals choose y , formally and intuitively? What is the likelihood function for this sample? What are the parameters you want to estimate? Assume that $\varepsilon \sim N(0, 1)$ and estimate the unknown parameters of the model. (*Hint: optimize over the probabilities, and then solve for the parameters.*)
