

Handout seminar 1, ECON4150

Herman Kruse

February 4, 2013

Introduction - list of commands

For *Question C* in the problem set, this handout will represent a solution proposal. The following list is meant to aid your individual solutions, as the .do-file the seminar-leaders have made is a mere guidance. We strongly encourage you to solve all Stata-problems on your own. If further explanation is needed, don't forget the *findit*- and the *help*-commands in Stata. They provide detailed descriptions on how to use commands.

- regress(reg) - used to actually do the regression between the two variables (regressand, regressor)
- mean - used to calculate the mean of a variable
- predict - used to predict some value after a regression, "xb" is optional and makes the predict-command use linear prediction
- egen - generates new variables
- twoway scatter - creates a scatter plot between two variables
- lfit - creates a linear line using OLS between two variables

These should suffice to solve all the problems for this seminar.

Note: *a useful tip is to always name your variables in such a way that you remember what they are. Take notice of how the variables in this solution proposal are named. Remember also that Stata is case-sensitive, so make sure you use as many small letters as possible. This will ease your typing.*

Solving the problems

`reg C I`

Problem 1

Source	SS	df	MS	Number of obs	=	47
Model	1279028.78	1	1279028.78	F(1, 45)	=	477.38
Residual	120567.778	45	2679.28395	Prob > F	=	0.0000
Total	1399596.55	46	30426.0121	R-squared	=	0.9139
				Adj R-squared	=	0.9119
				Root MSE	=	51.762

C	Coef.	Std. Err.	t	P> t	[95% Conf. Interval]
