## ECON 4310

## Labor supply elasticites

by
Steinar Strøm, fall 2004

This note is a supplement to the Labor supply note, section 1 Static model, single individuals, avaiable on the webside for the 4310 course.

Here we will derive the elasticites set out in the Labor supply note.
As before let
$\mathrm{U}=$ the utility level
$\mathrm{C}=$ disposable income=consumption
$\mathrm{h}=$ annual hours worked
L=leisure
$\mathrm{w}=$ hourly wage rate
$\mathrm{k}=$ non-wage income, hereafter called capital income.
$\mathrm{T}=$ taxes
The behavior of the individual follows from solving the following maximization problem:
$\mathrm{Max}_{\mathrm{h}} \mathrm{U}(\mathrm{C}, \mathrm{L})$
subject to
(1) $\mathrm{C} \leq \mathrm{wh}+\mathrm{k}-\mathrm{T}(\mathrm{wh}, \mathrm{k})$
(2) $\mathrm{L}=1-\mathrm{vh}$
(3) $v=\frac{1}{8760}$
(4) $\mathrm{h} \geq 0$

Eqs (2) and (3) imply that we have normalized annual leisure to vary between 0 and 1.
$T($.$) is the tax function. In practice this function is a stepwise linear function of wh. In$ Norway the tax function has the following structure:
(5) $\left\{\begin{array}{l}T=t_{k} k \text { for } w h \leq b \\ T=t_{k} k+t_{1}(w h-b) \text { for } b \leq w h \leq R_{1} \\ T=t_{k} k+t_{1}\left(R_{1}-b\right)+t_{2}\left(w h-R_{1}\right) \text { for } R_{1} \leq w h \leq R_{2} \\ T=t_{k} k+t_{1}\left(R_{1}-b\right)+t_{2}\left(R_{2}-R_{1}\right)+t_{3}\left(w h-R_{2}\right) \text { for } R_{2} \leq w h\end{array}\right.$

The marginal tax rate on capital income is $\mathrm{t}_{\mathrm{k}}$ and it is constant (proportional taxation), while taxation on wage income is progressive. Wage income below $b$ is not taxed. Wage income in the interval $\left(b, R_{1}\right)$ is taxed at the marginal tax rate $t_{1}$, wage income in the next interval $\left(R_{1}, R_{2}\right)$ is taxed at the marginal tax rate rate $t_{2}$, and wage income above $R_{2}$ is taxed at the marginal tax rate $t_{3}$. In a strict progressive tax system, $t_{1}<t_{2}<t_{3}$. In the tax literature the income intervals are called tax brackets. We observe that (5) gives a stepwise linear representation of the tax function in eq (1). Note that the policy instrument of the government are the tax rates $\left(t_{k}\right.$ and $\left.t_{i}, i=1,2,3\right)$ and the bounds of the tax brackets $(b$, $\mathrm{R}_{1}$ and $\mathrm{R}_{2}$ ).

Combining (1) and (5) we get
(6) $\mathrm{C}=\mathrm{m}_{\mathrm{i}} \mathrm{h}+\mathrm{I}_{\mathrm{i}} ; \mathrm{i}=0,1,2,3$.
where

$$
\text { (7) }\left\{\begin{array}{l}
\left\{\mathrm{m}_{0}=\mathrm{w} ; \mathrm{I}_{0}=\mathrm{k}\left(1-\mathrm{t}_{\mathrm{k}}\right)\right\} \text { for } \mathrm{wh} \leq \mathrm{b} \\
\left\{\mathrm{~m}_{1}=\mathrm{w}\left(1-\mathrm{t}_{1}\right) ; \mathrm{I}_{1}=\mathrm{k}\left(1-\mathrm{t}_{\mathrm{k}}\right)+\mathrm{t}_{1} \mathrm{~b}\right\} \text { for } \mathrm{b} \leq \mathrm{wh} \leq \mathrm{R}_{1} \\
\left\{\mathrm{~m}_{2}=\mathrm{w}\left(1-\mathrm{t}_{2}\right) ; \mathrm{I}_{2}=\mathrm{k}\left(1-\mathrm{t}_{\mathrm{k}}\right)+\mathrm{t}_{1} \mathrm{~b}+\left(\mathrm{t}_{2}-\mathrm{t}_{1}\right) \mathrm{R}_{1}\right\} \text { for } \mathrm{R}_{1} \leq \mathrm{wh} \leq \mathrm{R}_{2} \\
\left\{\mathrm{~m}_{3}=\mathrm{w}\left(1-\mathrm{t}_{3}\right) ; \mathrm{I}_{3}=\mathrm{k}\left(1-\mathrm{t}_{\mathrm{k}}\right)+\mathrm{t}_{1} \mathrm{~b}+\left(\mathrm{t}_{2}-\mathrm{t}_{1}\right) \mathrm{R}_{1}+\mathrm{t}_{3} \mathrm{R}_{2}\right\} \text { for } \mathrm{R}_{2} \leq \mathrm{wh}
\end{array}\right.
$$

In the tax-labor supply literature $m_{i}$ is called the marginal wage rate and $I_{i}$ the virtual income.

We will assume that the utility function has the follwing structure:

$$
\begin{equation*}
\mathrm{U}=\alpha \frac{\mathrm{C}^{\mu}-1}{\mu}+\beta \frac{\mathrm{L}^{\gamma}-1}{\gamma} \tag{8}
\end{equation*}
$$

where
(9) $\{\mu, \gamma\} \leq 1$
$\mathrm{Eq}(9)$ is a sufficient condition for a quasi-concave utility function.
The maximization problem now is
(10 $\left\{\begin{array}{l}\operatorname{Max}_{h}\left[U=\alpha \frac{\mathrm{C}^{\mu}-1}{\mu}+\beta \frac{\mathrm{L}^{\gamma}-1}{\gamma}\right] \\ \text { given } \\ \mathrm{C}=\mathrm{mh}+\mathrm{I} \\ \mathrm{L}=1-\text { vh }\end{array}\right.$
We should keep in mind that $m$ and I vary with respect to the optimal income and hence optimal hours.

The first order conditions (necessary conditions, but if (9) is fulfilled they are also sufficient conditions) are:
(11) $\frac{\partial \mathrm{U} / \partial \mathrm{L}}{\partial \mathrm{U} / \partial \mathrm{C}}=\frac{\mathrm{m}}{\mathrm{v}}$
or $u \sin g(8)$ and $L=1-v h$
(12) $\frac{(1-v h)^{\gamma-1}}{C^{\mu-1}}=\frac{m}{v}$

In addition
(13) $\mathrm{C}=\mathrm{mh}+\mathrm{I}$

Taking logs in (12) gives us the following representation of the first order conditions:

$$
\begin{align*}
& \text { (14) }(\gamma-1) \ln (1-v h)-(\mu-1) \ln \mathrm{C}=\ln \mathrm{m}-\ln v  \tag{14}\\
& \text { (13) } \mathrm{C}=\mathrm{mh}+\mathrm{I}
\end{align*}
$$

We are now ready to derive the elasticities. These elastcities have to be interpreted as giving the marginal change in optimal hours around the optimal point.

## 1) The uncompensated marginal wage elasticity (Cournot).

Inserting (13) in (14) and taking the derivatives of $h$ wrt $m$, and using the definition of an elasticity, which here says that $\mathrm{El}(\mathrm{h}: \mathrm{m})=\frac{\partial \mathrm{h}}{\partial \mathrm{m}} \frac{\mathrm{m}}{\mathrm{h}}$, we get immediately:
(15) $\mathrm{El}(\mathrm{h}: \mathrm{m})=\frac{1+(\mu-1) \frac{\mathrm{mh}}{\mathrm{C}}}{(1-\mu) \frac{\mathrm{mh}}{\mathrm{C}}+(1-\gamma) \frac{\mathrm{vh}}{(1-v h)}}$

The numerator can be negative or positive depending on the magnitudes of ( $\mu, \mathrm{mh}$ and C). The denominator is positive given that $(\mu, \gamma)<1$. (For those who are interested: Show that while $(\mu, \gamma)<1$ is a suffcient condition for a quasi-concave utility function, a necessary condition is that the denominator in (15) is positive.)

## 2) The virtual income elasticity.

Following the same procedure but now taking the derivative with respect to I and henceforth using the definition of an elasticity, we get
(16) $\operatorname{El}(\mathrm{h}: \mathrm{I})=\frac{(\mu-1) \frac{\mathrm{I}}{\mathrm{C}}}{(1-\mu) \frac{\mathrm{mh}}{\mathrm{C}}+(1-\gamma) \frac{\mathrm{vh}}{(1-v h)}}$
3) The compensated (utility constant) marginal wage elasticity (Slutsky).

Now, we cannot use (13), because we have to replace it by the condition that utility is kept constant, or
(17) $\bar{U}=U(C, L)$

Taking the derivatives in (17) wrt the marginal wage rate we get
(18) $\frac{\partial \mathrm{U}}{\partial \mathrm{C}} \frac{\partial \mathrm{C}}{\partial \mathrm{m}}+\frac{\partial \mathrm{U}}{\partial \mathrm{L}} \frac{\partial \mathrm{L}}{\partial \mathrm{m}}=0$
which implies
(19) $\frac{\partial \mathrm{C}}{\partial \mathrm{m}}=-\frac{\partial \mathrm{U} / \partial \mathrm{L}}{\partial \mathrm{U} / \partial \mathrm{C}} \frac{\partial \mathrm{L}}{\partial \mathrm{m}}$

But since (11) holds at the optimal point (before the marginal wage is changed), we get
(20) $\frac{\partial \mathrm{C}}{\partial \mathrm{m}}=-\frac{\mathrm{m}}{v} \frac{\partial \mathrm{~L}}{\partial \mathrm{~m}}=-\frac{\mathrm{m}}{v}\left(-v \frac{\partial \mathrm{~h}}{\partial \mathrm{~m}}\right)=\mathrm{m} \frac{\partial \mathrm{h}}{\partial \mathrm{m}}$.

Taking the derivative in (14) wrt m and using (20) and the definition of an elasticity, we get

$$
\begin{equation*}
\mathrm{El}(\mathrm{~h}: \mathrm{m} \mid \mathrm{U}=\overline{\mathrm{U}})=\frac{1}{(1-\mu) \frac{\mathrm{mh}}{\mathrm{C}}+(1-\gamma) \frac{\mathrm{vh}}{(1-v h)}} \tag{21}
\end{equation*}
$$

## 4) The consumption constant marginal wage elasticity (Frisch).

Holding C constant in (14) we immediately get

$$
\begin{equation*}
\mathrm{El}(\mathrm{~h}: \mathrm{m} \mid \mathrm{C}=\overline{\mathrm{C}})=\frac{1}{1-\gamma} \frac{1-v \mathrm{~h}}{v \mathrm{~h}} \tag{22}
\end{equation*}
$$
